

#### Abstract

Landings in the southwest Nova Scotia/Bay of Fundy spawning component in 2006 of 49,160 t were about the same as the previous year. The reduced quota has not been in place for a sufficient time to result in improvements to the biological characteristics of the population. There continued to be signs of deterioration in the state of the stock. Size distribution in the catch remained contracted, with little improvement in the proportion of larger and older fish in the fishery. The acoustic survey index from the spawning grounds in 2006 indicated a slight increase in spawning stock biomass (SSB) from 2005. There has also been little progress towards defined conservation objectives in recent years and most objectives are not being met.

There was an increase in landings to 9,800t from the offshore Scotian Shelf banks by purse seine, midwater and bottom trawl. The bottom trawl research survey catches demonstrated herring widely distributed over the Scotian Shelf but survey catches have declined substantially from the high of 2004.

There was an increase in surveyed acoustic biomass in the Halifax/Eastern Shore area while the Little Hope area saw a large decline. There was no survey effort and little catch in the Glace Bay area in 2006. The Bras d'Or lakes fishery was again closed and there was no sampling from this area.

The landings in the traditional New Brunswick weir and shutoff juvenile herring fishery remained low at 12,900 t and there is a trend of decreasing landings over the past ten years. There was a large proportion of small recruiting herring in the weir catches during the 2006 season.

## RÉSUMÉ

En 2006, les débarquements de géniteurs dans le sud-ouest de la Nouvelle-Écosse et dans la baie de Fundy se sont chiffrés à 49160 t , soit environ l'équivalent de ceux de l'année précédente. La réduction des quotas n'a pas été appliquée pendant une période suffisamment longue pour produire des améliorations au niveau des caractéristiques biologiques de la population. On observe encore des signes de détérioration de l'état du stock. La distribution des tailles des poissons capturés est demeurée restreinte, même si de légères améliorations sont survenues dans la proportion de poissons plus gros et plus âgés débarqués. L'indice du relevé acoustique effectué sur les frayères en 2006 indique une légère hausse de la biomasse du stock reproducteur par rapport à 2005. Au cours des dernières années, on a également enregistré peu de progrès relativement aux objectifs de conservation établis, et la plupart de ces objectifs n'ont pas été atteints.

Les débarquements de poissons provenant des pêches à la senne coulissante, au chalut pélagique et au chalut de fond menées sur les bancs au large du plateau néo-écossais ont connu une hausse pour s'établir à 9800 t . Malgré un déclin important depuis le pic de 2004, les prises au chalut de fond effectuées lors des relevés scientifiques démontrent que le hareng est fortement répandu sur le plateau néo-écossais.

On enregistre une augmentation de la biomasse calculée au moyen de relevés acoustiques dans la zone de Halifax et de la côte est, tandis que la zone de Little Hope affiche un déclin important. Aucun effort d'échantillonnage n'a été consenti et de faibles prises ont été enregistrées dans le secteur de Glace Bay en 2006. La pêche a de nouveau été interdite dans le lac Bras d'Or, et l'on n'a pas effectué d'échantillonnage dans cette zone.

Au Nouveau-Brunswick, les débarquements de la pêche au hareng juvénile traditionnelle à la fascine et à la senne de plage sont demeurés faibles, à 12900 t , et l'on observe une tendance à la baisse pour ce qui est des débarquements au cours des dix dernières années. On a observé une grande proportion de petits harengs recrues dans les prises à la fascine durant la saison 2006.

## 2006 Evaluation of 4VWX Herring

## Introduction

Atlantic herring is a pelagic species found on both sides of the North Atlantic. Herring spawn in discrete locations, to which they are presumed to home. Herring first mature and spawn at three or four years of age ( 23 to 28 cm or 9 to 11 in ), then begin a predictable annual pattern of spawning, overwintering, and summer feeding, which often involves considerable migration and mixing with members of other spawning groups. Most fishing takes place on dense summer feeding, overwintering, and spawning aggregations.

The 4VWX management unit contains a number of spawning areas, separated to various degrees in space and time. Spawning areas in close proximity with similar spawning times, and which share a larval distribution area, are considered part of the same component. These undoubtedly have much closer affinity than spawning areas that are widely separated in space or time, and do not share a common larval distribution. Some spawning areas are large and offshore, whereas others are small and more localized, sometimes very near shore or in small embayments. The situation is complicated further as herring migrate long distances and mix outside of the spawning period both with members considered part of the same component and with members of other components. For the purposes of evaluation and management, the 4 VWX herring fisheries are divided into four components (Figure 1):

1. SW Nova Scotia/Bay of Fundy spawning component
2. Offshore Scotian Shelf banks spawning component
3. Coastal (South Shore, Eastern Shore and Cape Breton) Nova Scotia spawning component; and
4. SW New Brunswick migrant juveniles.

Each component has several spawning areas, and there is mixing of fish among spawning components. Industry and management have explored means of managing the complexity within each component (such as distributing fishing effort among spawning areas according to their relative size) and of taking appropriate account of interaction among components (such as fishing restrictions on some areas of mixing). Fisheries in the 4 VWX area in recent years have been dominated by purse seine, weir and gillnet, with relatively minor landings by shutoff, trap and midwater trawl.

The Georges Bank spawning component is not included in this evaluation except to document Canadian fishing activity. As in 2005, there were no herring landings in 2006 from the Canadian portion of Georges Bank (Table 1). This fishery is included in the Gulf of Maine stock complex and has been recently evaluated separately (DFO 2003a, TRAC 2006).

## 1) Objectives and Management

The 2003-2006 Scotia-Fundy Herring Integrated Fisheries Management Plan (DFO 2003b) sets out principles, conditions, and management measures for the 4VWX herring fisheries. The main principle stated in the plan is "the conservation of the herring resource and the preservation of all of its spawning components".

Three conservation objectives developed and reviewed by Sinclair (1997) appear in the plan:

1) To maintain the reproductive capacity of herring in each management unit through:

- persistence of all spawning components in the management unit;
- maintenance of biomass of each spawning component above a minimum threshold;
- maintenance of a broad age composition for each spawning component; and
- maintenance of a long spawning period for each spawning component.

2) To prevent growth overfishing:

- continue to strive for fishing mortality at or below F0.1

3) To maintain ecosystem integrity/ ecological relationships ("ecosystem balance").

- maintain spatial and temporal diversity of spawning
- maintain herring biomass at moderate to high levels

There is evidence that most of these objectives are not being met despite the efforts that have been made in recent years including a reduced TAC. There is also a need to better define these objectives in terms of minimum thresholds and to explicitly list the spawning components in terms of spatial and temporal expectations.

An "in-season" management process, first implemented in the southwest Nova Scotia fishery during 1995, continued to be used widely within the 4 VWX management area (DFO 1997, Stephenson et al. 1996, 1999). The approach encouraged surveying using the commercial fleet under scientific direction prior to fishing ("survey, assess, then fish" protocol) to ensure that effort was distributed appropriately among various components of the stock (particularly among spawning components) according to the relative size and current state of each component. The use of this approach in recent years has improved data collection and enabled modifications to management decisions to be made with the involvement of participants and on the basis of up-to-date information.

Collaborative research efforts with the fishing industry have been important in recent years. A major portion of the herring industry (including the purse seine sector and major processors) forms the Herring Science Council (HSC), and some members of the fixed gear sector have undertaken a separate Joint Project Agreement with DFO to undertake collaborative scientific projects. The herring industry has continued to provide biological sampling and samples while the purse seine and gillnet sectors undertook key acoustic surveys. Under the auspices of the HSC a dedicated field biologist also takes part in initiatives such as tagging, a summary of fleet activities and analysis of acoustic records from fishing trips.

## 2) SW NOVA SCOTIA/BAY OF FUNDY SPAWNING COMPONENT

### 2.1 The Fishery

Herring fishing locations, NAFO unit areas for catch and sample aggregation, and fishing ground areas are used to describe fishing activities and group the data for analysis (Figures 2-5). Landings for the 2005/06 quota year (from Oct. 15, 2005 to Oct. 14, 2006) were 49,160t for the SW Nova Scotia / Bay of Fundy component (Table 1). There were additional landings of 29,360t
in the non-stock components for an area total of 78,520t. Landings for the current 2006/07 quota year were 2,300t as of March 28, 2007 (Table 2).

Landings have tracked the TAC in recent years with most of the quota being taken for each year since 2002 (Table 3, Figure 6). Total landings from this component in 2005 and 2006 are among the lowest on record since 1963. Most of the catch over the history of this fishery has been caught by purse seine gear with the 4 X summer purse seine component being the most important (Figure 7). Landings by the purse seine sector accounted for most of the component catch in 2006 (Figure 7, 8), with minimal landings by the gillnet sector (720t) and the Nova Scotia weirs ( 2,500 t) (Table 1). Eighty percent of the catch limit was initially allocated to the mobile gear sector and $20 \%$ to the fixed gear sector, as has been done historically. Transfer of unused quota to the mobile fleet occurred in September, near the end of the fishing season.

Purse seine catches are summarized by fishing grounds using definitions of the various grounds based on groupings of 10 minute boxes of latitude and longitude (Figure 5). The spatial distribution of the purse seine fishery in 2006 was similar to the previous year with the largest catches occurring on German Bank and around Grand Manan (Table 4, Figure 9). Landings of about 16,500 t from the German Bank area made up about $35 \%$ of the catch. There was a substantial decrease in the 2006 landings for Scots Bay to 3,400 trom the high of 24,900 t recorded for this area in 2004 and there was also a large decline in landings from the Long Island area to only 1,900t. Small increases in landings of summer feeding fish from the Gannet/Dry Ledge and Lurcher areas were recorded. Catches of non-stock component herring by purse seine came mainly from the offshore Scotian Shelf area (Table 5).

During the 1970's and 1980's, a large purse seine fishery took place on over-wintering aggregations in Chedabucto Bay. In recent years however, there has been no fishing effort in this area as traditional vessels have been successfully fishing elsewhere and because the reduced TAC has resulted in conserving of quota for later in the season. In some years there has been a small fishery on over-wintering herring in January off Halifax Harbour (Chebucto Head), but the majority of the fall and winter herring landings for the past several years have come from the New Brunswick side of the Bay of Fundy.

In the 2005-2006 quota year, purse seine landings of 470t were reported in Oct. 2005 and 460t in Jan. 2006 (Table 1, Figure 10, 11). The summer purse seine fishery took place in similar areas as in previous years (Figure 11). A large part of this fishery was directed on the major spawning grounds in Scots Bay and on German Bank where recent catches are primarily within the pre-defined acoustic survey catch areas (Melvin and Power 1999).

Scots Bay:
The Scots Bay herring purse seine fishery has been an important component of the summer fishery with catches since 1987 ranging from 1,000 to 24,400 t during the period of early July to late August-early September (Table 6, Figure 12, 13). The peak year of 2004 was unusual in several aspects, with the highest recorded catch of 24,400 t and the longest season extending to Sept. 16. In 2004, the distribution of catches was also more widespread extending both north and east of the innermost strata survey area (Figure 12). In 2005 the overall catch was reduced to only 5,870 t and was limited to areas to the north and east of the main survey area. The fishing season also started later and was of shorter duration than in previous years.

The 2006 fishery was similar in overall duration to the previous year with catches scattered within the defined spawning area but there was a reduction in overall fishing activity with $3,350 \mathrm{t}$
landed and less than half of the number of landings (slips) than in the previous year (Table 6). Several external factors contributed to a decrease in fishing activity and survey effort including a reduced roe market, lack of access to the Digby wharf to offload herring, the distance to market and the re-introduction of Herring Fishing Area 22 (HFA-22) line The duration of the spawning fishery period in Scots Bay was the same as in 2005 but there was no observed spawning or catches of spawners in the spawning box in the middle of the period during early August (Figure 14). The combination of these factors resulted in fewer vessels fishing in Scots Bay and participating in the surveys and therefore there was less survey and catch information collected about Scots Bay spawning aggregations in 2006.

German Bank:
German Bank is usually the location of one of the major summer herring purse seine fisheries with catches since 1985 ranging from 9,000 to 36,000 t during the overall fishery period of early May to late October (Table 7). Catches during the spawning period from August 15 to October 31 have been reduced since the reduction in the quota in 2003 with about 12,000t landed from the main strata survey area. The percentage of the total German Bank catch taken during the spawning period has remained steady between 50 and $70 \%$, but the percent contribution of the German Bank catch to the overall landings has been increasing, reflecting an increased reliance on this area (Table 7, Figure 15).

Catches in 2006 for the pre-spawning period prior to Aug. 15 were concentrated mostly within the defined survey box area (Strata area). This differed from previous years since about 2000 when catches were more widely scattered over the larger catch area (Figure 16). Catches during the spawning period in 2006 were very similar to those of 2005 with two localized groups of presumed spawning herring seen within the Strata area and more scattered groups seen north of the survey box (Figure 17). These scattered groups are usually shown from sampling to be pre-spawning or juvenile sized herring.

Daily catches in 2006 were spread out through the spawning season with an early cluster of catches from mid to late August, which was not seen in 2004 or 2005, (Figure 18). The daily landings at the end of the season appeared to be reduced compared to recent years, with totals of less than 500t per day.

Trinity Ledge:
The Trinity Ledge spawning ground is still considered to be recovering and is closed to purse seine gear from Aug. 15 to Sept. 15. In 2006 there were acoustic surveys followed by some catch by drift gillnet gear. The herring gillnet fishery in the Trinity Ledge and Spectacle Buoy fishing area took place between June 3 and Sept. 21, 2006 with total landings of 719 t (Table 1, Figure 19). On Trinity Ledge catches began around Sept. 7 with landings of less than 50t/day until Sept 14; these then increased to about 100t/day with some gaps until Sept 21 (Figure 20).

Outside of this component additional catches by drift gillnet gear occurred in Sept. to Oct. in the Little Hope/Port Mouton spawning grounds. There were also set gillnet catches along the Eastern Shore to the east of Halifax and near Glace Bay in Cape Breton (Figure 21).

Spectacle Buoy:
A spring gillnet fishery for roe has occurred in recent years for a short period in June in the vicinity of Spectacle Buoy, southwest of Yarmouth, N. S. This fishery is dependent upon the availability of roe herring and to some extent, market conditions, and may or may not occur in any given year. In 2005, a single survey of the Spectacle Buoy area was undertaken on June 6 which estimated a total survey biomass of only 292 t in an area of $0.57 \mathrm{~km}^{2}$. Landings were minimal in the Spectacle Buoy area in June 2006 with less than 10t reported and no surveying completed. A single acoustic survey of Spectacle Buoy was completed on Sept 10, 2006 during the fall spawning season. Purse seine vessels also explored the area on Sept. 15 during one of the German Bank surveys but documented no herring.

Nova Scotia weirs:
Catches in the Nova Scotia weirs of 2,500 t were just below average after the record lows of 2000 and 2003 (Table 8; Figure 22). The annual variation in catch has been attributed to problems in availability of fish to this fixed stationary gear as there are usually substantial purse seine catches in the nearby Long Island area on the Bay of Fundy side of Digby Neck. The seasonal timing of the Nova Scotia weir landings has shifted in the last 4 years with a higher proportion of landings now as late as August. and September, compared with the traditional early fishery seen in May and June previously (Table 8). Catches in recent years for the Nova Scotia weirs have been highly variable and not as consistent in their amount or timing as in the previous decade. There has been a decline in the total number of herring weirs but the catch per weir ( $t$ ) for the Nova Scotia weir fishery has been above average in recent years (Table 9).

## Catch and Effort

Catch and effort for gillnet data in the SW Nova Scotia/Bay of Fundy spawning component were examined in previous assessments and showed little trend and are considered unrepresentative due to the very small amount of catch and effort (Power et al., 2004). This trend of reduced catch and effort continued in the 2006 fishing season and so this data was not reexamined.

Purse seine landings make up most of the overall catch and are allocated $80 \%$ of the TAC in the SW Nova Scotia/Bay of Fundy component under the current management plan. The purse seine catch has fluctuated between 45,000 t and 100,000 t since 1989 reflecting changes in the TAC (Table 10, Figure 23). The overall number of boats fishing and days fished has been dropping since 1990 due to fleet rationalization. This has resulted in increases in catch per boat and catch per day in recent years. In general, purse seine catch rates are not considered to reflect trends in population abundance due to the nature of herring schooling behavior and the acoustic technology to find these schools with catch rates remaining high or stable at even low stock levels.

### 2.2 Resource Status

## Acoustic Surveys

Automated acoustic recording systems deployed on commercial fishing vessels were used to document the distribution and abundance of herring by industry vessel surveys (Power et al. 2007). Scheduled surveys were conducted every 2 to 3 weeks on the main spawning components and an index of spawning stock biomass for each component was estimated by summing these results (Table 11). A major source of uncertainty continues to be the
assumption that the biomass estimates from the surveys are simply additive. If herring remain on the spawning grounds for more than one survey then the estimate of total SSB will be significantly biased upward due to double counting. If herring move on and off the spawning grounds between surveys then the estimate of total SSB will be an underestimate. As well, in recent years herring have been observed close to bottom, making them difficult to enumerate acoustically which may also lead to an under-estimation of biomass from acoustic surveys.

In 2006, three surveys were conducted in Scots Bay, a reduction of one survey over the previous two years. Four surveys were completed on German Bank. Additional data from fishing or survey nights in Scots Bay, German Bank, Browns Bank, Seal Island and Spectacle Buoy areas were examined. Five surveys were conducted on Trinity Ledge and the documented amount of spawning fish was higher for this area than the past two years but survey area coverage was again limited. There were no surveys and no reports of spawning herring on Lurcher Shoal. The Seal Island and Browns Bank area grounds had only fishing night estimates of presumed spawning fish. For German Bank and Scots Bay areas these surveys provided good coverage of the spawning areas consistent with previous years and with established protocols. Biomass estimates for Scots Bay, Trinity Ledge and German Bank were approximately 28,600 t, 8,500 t, and 245,500 t for an estimated total SSB of 282,600 t in the traditional survey areas, which is an increase from 2005 but still well below average for the eight year series (Table 11, Figure 24).

From 1999 to 2003, acoustic survey results were used as minimum estimates of absolute SSB abundance and the population was considered to be approximately 500,000t. An SSB of that size would have been expected to result in substantial growth of the population, improved age composition and low fishing mortality, given reasonable recruitment and the landings over that period. The expected growth in the population has not been observed in the surveys and an increase in proportion of larger/older fish has not been observed in either the surveys or the fisheries. The small proportion of larger/older fish in the population indicates that the total mortality on this stock is high.

## Spawning ground turnover rates

The current acoustic survey method on spawning grounds is dependent on periodic turnover of spawning fish on the grounds. Acoustic surveys are required to be separated by at least 10 to 14 days to allow for turnover and to prevent double counting (Power et al. 2002). This aspect of the assessment method was the subject of investigation in 2001 and of intensive sampling for maturity stage since the 2002 fishing season. The results are summarized by Melvin et al. (2003, 2004, Power et al. 2005) and were used to assist in the evaluation of turnover timing and the inclusion or exclusion of specific acoustic surveys.

In 1998 and 2001 spawning herring were tagged on German Banks as part of a cooperative project between the Pelagics Science Council/Herring Science Council and Fisheries and Oceans, Canada. After the 1998 tagging event, $29 \%$ of the tag returns were caught on the spawning grounds more than ten days after tagging and $21 \%$ were caught more than fourteen days after (Paul 1999). In contrast in 2001 all tag returns were from within 8 days of tagging but these results were complicated by a large decrease in fishing effort in the second week after tag application (Power et al. 2002, Waters and Clark 2005).

In response to a recommendation from the 2005 RAP, tags were applied to herring on the spawning grounds of Scots Bay and German Bank (Clark, 2006). The results from the tag returns indicated that some tagged herring remained on the spawning grounds for at least 3
weeks after tagging, and in some cases, up to five to six weeks after tagging. As a result, acoustic surveys that were spaced at 2 week intervals were surveying some of the same fish twice. These results also indicated a possible affinity between some of the fish tagged in Scots Bay and the New Brunswick weirs.

These results have serious implications in how the acoustic surveys are evaluated and used to determine stock status. Some preliminary analysis has been completed comparing three different approaches for the interpretation of the acoustic biomass estimates in an absolute sense (Power et al, 2006b). The results showed that caution is warranted when employing the cumulative biomass estimates as absolute in any of the survey areas. The results also indicated that some proportion of herring remain in the survey area even three weeks or longer.

A framework assessment meeting in January 2007 determined that double counting does occur but the extent has not been well determined (DFO, 2007). However, it was recommended that surveys continue to be conducted at 10-14 day intervals to avoid double sampling. The timing/turnover issue was considered to be of highest importance for further study which should include work on the duration of the maturation process, further tagging with more frequent intervals to estimate turnover rates and increased survey frequency to reflect maturity stage duration.

## Exploitation Rates on Spawning Grounds

The acoustic survey estimates and catches from individual spawning areas were examined in an attempt to estimate partial exploitation rates on the different spawning groups and for the overall complex. This information can be used to assess the impact of fishing and to estimate the relative size of individual spawning units within the complex (Table 12). For this analysis only the three spawning components for Scots Bay, German Bank, Trinity Ledge which have received relatively consistent survey effort since 1997 were included. Since there are also issues regarding comparability of acoustic surveys, in terms of the area of survey coverage among years, only data since 1999 were included in the overall averages (Table 12-A1). Catches throughout the year directly from the spawning grounds areas were assumed to be site specific (Table 12-C1), while catches from all other areas were considered non-spawning and were allocated based on the relative spawning ground SSB proportions (Table 12-A2, C2). In addition the SSB for Seal Island and Spectacle Buoy were allocated to the German Bank spawning area. The exploitation rates were calculated from both the actual catch on the spawning grounds and the overall adjusted catch as a simple proportion (Catch / SSB) (Table12-P1, P2).

Calculation of exploitation rates by component since 1999 (Table 12-P2) showed that the larger grounds (German Bank and Scots Bay) had an average exploitation of 15 to $23 \%$ while Trinity Ledge was calculated as $51 \%$. Individual values for specific years and areas were highly variable (from 12 to $146 \%$ ) due to catch allocation as well as inconsistent survey effort over the period. The overall exploitation rate for the $4 W X$ stock ranged between 14 and $21 \%$, which is close to the target of $\mathrm{F}_{0.1}=0.22$ (exploitation of $18 \%$ ). These rates are dependent on the assumptions that the acoustic survey SSB is complete, that catches have been properly allocated and most critically, that the acoustic SSB provides an absolute measure of biomass.

## Sampling

Comprehensive biological sampling continued with substantial involvement of the fishing industry. In 2006 a total of 1,250 samples ( 147,500 fish) were measured for length while 5,510 fish were sampled for sex, weight, maturity and age (Table 13). The sources of the samples are
shown in Table 14, with the bulk coming from the processing industry, as has been the case since 1996 Additional samples were collected by: DFO personnel, observers deployed on purse seine vessels and from DFO research surveys. Sampling from the commercial fishery was well matched to the spatial and temporal distribution of the fishery. Additional sampling from research vessel surveys during the spring and summer resulted in widespread geographic coverage as in the past (Figure 25).

## Catch at Age

Recent developments since the April 2006 herring RAP have identified inconsistencies in ageing that may have an impact on the age based assessment results. The impact of these comparisons will be further investigated, but it is unlikely they will be resolved until the winter of 2008/09 (DFO, 2007). In the interim any analysis using age data is considered unreliable and other approaches will be applied (Melvin and Power, 2007).

However, for comparison purposes and consistent with previous assessments, the catch at length and age was constructed using the 'Catch at Age' application (version 10.4) which is a Population Ecology Section program for computing catch at age statistics as part of the stock assessment process. Data files used by 'Catch at Age' were selected directly from biological sample data in the Pelagic Samples Database. These data included a $2 \%$ adjustment for the shrinkage due to freezing on the length measurements for frozen samples (Hunt et al. 1986). The length-weight relationships, which are also required as input to the 'Catch at Age' application, were calculated using an Oracle SQL*Plus script. Due to a lack of ageing in 2006 the catch at age was not available. Runs were made using the 2005 ages as the default in order to create catch at length keys for use with the analysis. The catch at length/age statistics were then calculated from length frequency and age-length key samples expanded to total catch using appropriate monthly length-weight relationships. The data were grouped and monthly agelength keys were applied to length frequencies to produce catch at age and catch at length statistics by NAFO unit area, gear-type and month.

## Historical Age Composition

The historical time series of catch at age for the period 1965-2005 shows very few fish older than age 7 in recent years and has been dominated by ages 2 through 4 since 1998 (Table 15, Figure 26). The series is now primarily made up of fish age 6 and younger but older ages were a feature when strong year-classes (i.e. 1976 and 1983) were progressing through the fishery. The rapid decline of year-classes (including the presumed moderately strong 1998 year-class) implies a high total mortality (Power et al, 2006a).

The trend toward catches at younger ages results in reduced yield and is reflected as a decrease in the average weight of fish in the overall catch at age (Figure 27). This indicator has declined from an average fish weight of 160 to 180 g in the 1980's and 1990's to an average fish weight of about 90 g in the 2003. These levels had not been observed since 1975, just prior to the closure of the meal fishery, the implementation of individual boat quotas and the conversion to a food fishery by the industry (lles 1993). If there is a recruitment fishery on younger ages, a lack of knowledge on the size of the incoming year-classes is a cause for concern. However, the most recent years have seen a trend toward a larger average fish size with the 2006 average size near the long term average of 125 g .

## Size composition of catch

The size composition of the catch was determined from the length sampling data and was calculated for the stock component using the appropriate catches and monthly length weight relationships. The 1992 catch at length was also determined for comparison with the current data. The time around 1992 is considered to be a period when the stock was known to have a broad size and age distribution but was also in a state of decline (Power et al 2006a). The catch at length for 1992 had a broad distribution of sizes from less than 10 cm to 38 cm with a substantial proportion (21\%) greater than 30 cm (approximate mean size for a $5-6$ year old herring) (Table 16, Figure 28).

In 2006, the catch at length was composed of $35 \%<23 \mathrm{~cm}$ (50\% maturity at length), $63 \%$ from 23 to 30 cm and $1.7 \%$ for sizes larger than 30 cm (Table 16, Figure 29). There has been an absence of older/larger fish in the catch since 1999 (Figure 30). The length distribution in the catch for sizes greater than 30cm declined between 2000 and 2003 and remains low at around 2\% (Figure 31).

Prior to 2005, there was targeting of young fish and the high proportion of juveniles in the catch resulted in lost potential yield. In 2005/2006 industry made a concerted effort to re-direct to larger fish which resulted in a significant decrease in the proportion of fish less than 23 cm in the catch, which had been as high as $60 \%$ in 2003 (Table 16). This, combined with the reduced TAC, has led to an increase in the proportion of adult fish from 23 to 30 cm in the catch (Figure 31). The total removal of fish by numbers was also reduced by close to $50 \%$ in 2005/2006 relative to 2004 (Table 16).

## Stock Trends

A population model (Virtual Population Analysis, VPA) was conducted on this stock component in 2005 (Power et al., 2006a). Estimates of relative abundance from the acoustic surveys were used to calibrate the analysis. While the trends in modelled abundance followed those in the survey, there was an inconsistency in the absolute estimate of biomass determined by the VPA and the absolute estimate provided by the acoustic survey. This inconsistency has not been resolved but may be due to issues with the survey (e.g. double counting, target strength) and/or the VPA (e.g. ageing, unaccounted mortality).

In April of 2006, ageing inconsistencies were identified that may have an impact on the age based assessment results (DFO 2006) (Figure 32). The terms of reference for the 2007 RAP assessment meeting requested "An evaluation of the southwest Nova Scotia / Bay of Fundy spawning component, including an evaluation of the implications of the aging errors uncovered in 2006 on the current VPA-based assessment formulation." (Melvin and Power, 2007) To test the sensitivity of the VPA to changes in the age input, several growth models using age-length keys from selected years were applied to the catch at age and the indices of abundance from 1999 to 2006 and input into the 2005 VPA formulation. The estimated fishing mortalities for 1995-2006 from these simulations (Figure 33) were variable and consistent with the previous investigation (Figure 32), and no scenario produced fishing mortalities at or below $\mathrm{F}_{0.1}$ ( $\mathrm{F}=0.23$ ).

Fishing mortality remains high and is considered to be well above $F_{0.1}$. This is supported by the simulations and the contracted size range observed in the catch and survey (Figure 29). The recent increase in abundance of herring in the $23-30 \mathrm{~cm}$ size range is a positive signal for potential future population growth (Figure 31). On balance however, the stock is still low relative to historical levels.

### 2.3 Sources of Uncertainty

The potential benefits of the reduced quota in 2005 and 2006 will take time to be reflected in the biological characteristics of the population. The acoustic survey index provides fisheries independent information on the spawning stock biomass but does not provide data on younger age classes. The size of herring year-classes is highly variable and there is no index of recruitment. Anecdotal information of widespread abundance of small fish and significant catches of small fish in the New Brunswick weirs of the 2005 year class may indicate the presence of a strong year-class. However, large numbers of young fish in the 1980 New Brunswick weir catch did not translate into a strong year class in the southwest Nova Scotia / Bay of Fundy spawning component.

### 2.4 Ecosystem Considerations

Herring is prominent in the diet of many fish, seabirds and marine mammals, and should be managed with these interactions in mind. At present, use of a natural mortality rate of 0.2 and maintenance of SSB at moderate to high levels are assumed to account for these interactions.

Recent management initiatives to protect spawning components are intended to maintain the spatial and temporal diversity of herring spawning. Increased fishing on juveniles, which are of mixed or unknown stock affinity, is inconsistent with this objective.

### 2.5 Outlook

Recent assessments of the SWNS/BOF spawning component suggested that fishing mortality should remain below $\mathrm{F}_{0.1}$ (about 20\% exploitation rate) for a number of years in order to rebuild spawning stock biomass in all spawning areas and to expand the age composition so as to meet the explicit biological objectives of management (Power et al, 2006a).

The rapid decline in year-classes (failure to reach older ages), even with relatively strong recent year-classes, indicates high total mortality. It seems that the current catch is substantially higher than would be consistent with a moderate F. Recent catches have been mostly consistent with the survey, assess, fish protocol of less than $20 \%$ of surveyed biomass. However the size of fish reflected in the catch at age/length indicates that total mortality may be considerably higher.

### 2.6 Management Considerations

An evaluation of progress in recent years against biological objectives in the management plan (DFO 2003b) indicate that most objectives are not being met (Table 17). The biomass estimates for all spawning areas increased slightly from 2005 but are still at historically low levels with a substantial decline from 2004. The Scots Bay, Trinity Ledge, Lurcher Shoal and Seal Island spawning grounds remain at very low biomass. In 2006 the beginning and duration of spawning in Scots Bay and German Bank occurred as normal, unlike 2005, but there was a mid-season gap in spawning in Scots Bay. Fishing mortality is likely high and well above $F_{0.1}$ and the SSB is near the lowest recorded level since 1999 from acoustic surveys.

The proportion of larger $(30 \mathrm{~cm}+)$ sizes in the catch has contracted and is very low and the age composition is assumed to be truncated with an absence of larger fish in the population. The recent increase in abundance of herring in the $23-30 \mathrm{~cm}$ size range is a positive signal for potential future population growth.

The in-season management approach, which spreads the effort in the fishery spatially and temporally among spawning components, is seen as beneficial in achieving the conservation objectives. The "survey, assess, then fish" protocol is effective in spreading the catch appropriately among spawning components in proportion to their relative size and is considered an important safeguard.

Acoustic surveys have become critical to stock status evaluation. Surveys conducted in 2006 conformed to the proposed survey design. It is important that there be continued attention to coverage and survey design in order to assure year-to-year consistency in all spawning areas.

## 3) OFFSHORE SCOTIAN SHELF BANKS SPAWNING COMPONENT

### 3.1 The Fishery

A foreign fishery during 1963-1973 is estimated to have removed as much as 60,000t per year from the offshore Scotian Shelf banks (Stephenson et al. 1987). Few herring were caught after the extension of jurisdiction in 1977 until 1996, when a fishery was initiated by the 4WX purse seine fleet and 11,700t were taken (Table 3). Since 1996, a fishery has taken place on feeding aggregations on the offshore banks, primarily in May and June, with catches ranging from 1,000 to 20,000 t. The variability in catch levels was often due to problems of fish being too deep, weather and market conditions rather than in the abundance of herring in these areas.

Total landings in 2006 increased to 9,800 t with most landings by purse seine and midwater trawl in May to July, in the vicinity of the Patch, Emerald and Western Bank (Figure 34, 35). Landings of the 2006 fishery on the Scotian Shelf Banks were near the ten year average (approx. 9,000t) (Figure 36). In 2006, herring continued to be caught as by-catch in the domestic bottom trawl fishery on the Scotian Shelf edge and slope with 42t reported (Table 1). There was also effort in the late fall by midwater trawlers with 885t caught in the offshore area east of Sable Island (Table 1, Figure 35). Records by observers on herring and mackerel directed trips by both purse seine and midwater trawl gear types in the offshore showed a mixture of species and discards were low relative to the overall kept catch (Table 18).

In 2006, the size composition of the catch from the offshore Scotian Shelf banks showed mostly adult fish $>23 \mathrm{~cm}$ ( $50 \%$ maturity at length) with a substantial proportion (23\%) larger than 30 cm and a modal size of 28 cm (Figure 37).

### 3.2 Research and Industry Surveys

## Industry Surveys

There have been no industry surveys of the offshore Scotian Shelf area since 2001. Acoustic recorders were activated in 2006 on a few occasions but insufficient quantities of fish were observed to warrant analysis or the information was of poor quality with excessive interference from other electronics. Acoustic records were made by the Julianne III, a purse seine/midwater trawl vessel, during operations in the offshore. A large aggregation was reported and recordings were made in an area east of Sable Island along the shelf edge during Nov. and Dec. 2006. The acoustic system, which is a Simrad 200 kHz ES60, has yet to be calibrated and so the data have not been analyzed. Consequently, no acoustic biomass estimates were available from the Scotian Shelf in 2006 (Power et al. 2007).

## July Bottom Trawl Survey

Previous results from the summer research bottom trawl survey showed few herring on the Scotian Shelf during the 1970's, increasing amounts during the 1980's and a relatively widespread distribution in recent years (Harris and Stephenson 1999, Power et al. 2004, Stephenson et al. 2001). In 2005, offshore herring catches from this survey showed a substantial decline from the high in the previous year (Table 19, Figure 38). Inter-vessel conversion factors established for differences in fishing efficiency by species are being developed from the comparative surveys completed in 2005.

The decreasing trend for the most recent years from the bottom trawl survey is also similar to the trend seen in NAFO areas 4 W and 4 X for the combined strata (Table 19, Figure 39). The strata areas used for selection of trawling stations in this bottom trawl survey series are shown in Figure 40 (Doubleday 1981). Herring catches from the 2006 summer survey were again widely distributed on banks west of Sable Island (Figure 41) and were comparable to average catches from the last nine years (Figure 42). Size distribution of catches from the research trawl survey shows a distribution similar to that seen in the catch with a large proportion greater than 30cm (Figure 43).

## Fall Herring Research Survey

Since 2002, there has been no fall herring research survey on the Scotian Shelf when the research vessel Alfred Needler was last used to explore the various inshore and offshore areas where herring were known to aggregate.

### 3.3 Outlook and Management Considerations

The summer bottom trawl research survey demonstrates that there is a considerable abundance of herring widely spread over the offshore banks of the Scotian Shelf. Information from previous assessments indicated the presence of at least some autumn spawning on Western Bank in recent years. There is very little new information to add and no reason to change the previous outlook:

- Recorded landings in the foreign fisheries of 13,000t to 60,000t between 1969 and 1973 did not appear to be sustainable.
- The initial catch allocation for 2006 should not exceed the 12,000 t reference value used in the recent fishing plans.

There continues to be insufficient documentation of stock size, distribution and spawning behavior for this component. There have been no industry surveys of the offshore Scotian Shelf area since 2001. Industry, DFO Science and Management are encouraged to continue to work together to improve the biological basis for management. The industry should be encouraged to explore and undertake surveys of the offshore area.

## 4) COASTAL (SOUTH SHORE, EASTERN SHORE AND CAPE BRETON) NOVA SCOTIA SPAWNING COMPONENT

### 4.1 The Fishery and Resource Status

There is no quota for the coastal Nova Scotia spawning component and, apart from four areas; the size and historical performance of various spawning groups are poorly documented. In addition to the traditional bait and personal-use fisheries, directed roe fisheries have occurred on several spawning grounds in recent years.

In addition to traditional coastal fixed gear fisheries for subsistence and personal bait, there has been an increase in the number of active gillnet licenses in recent years aimed at spawning herring for the roe market (Clark et al. 1999). As the inshore roe fisheries off Glace Bay, East of Halifax and Little Hope have developed, participants have contributed to sampling and surveying and the fisheries have attempted to follow the 'survey, assess, fish' protocol. This was the eleventh year for a fishery on spawning fish off Halifax/Eastern Shore and the tenth year of gillnet roe fisheries off Little Hope/Port Mouton and Glace Bay.

The recorded landings $(6,600$ t) in 2006 in the four major gillnet fisheries along the coast of Nova Scotia were about the same for the Eastern Shore area, minimal for Glace Bay, but higher for Little Hope/Port Mouton (Table 20). The Bras d'Or Lakes fishery remained closed.

Little Hope
The 2006 herring gillnet fishery in the Little Hope/Port Mouton fishing area took place primarily between Sept. 28 and Oct. 28, 2006 with total landings of 3,133t (Figure 44). This is primarily a herring roe fishery with catches reported from two main areas; near Little Hope Island and east of Liverpool. Daily landings were less than 100t/day until Oct. 4, and then increased to about $150-300 \mathrm{t} / \mathrm{day}$ with some gaps until Oct. 27. The roe fishery finished on Oct. 28 but there continued to be small amounts landed for bait.

Acoustic surveys were completed in each of the primary fishing areas near Little Hope/Port Mouton on Oct. 7, 17, 19, 22 and 25 with total SSB estimated as 21,700 t, a large decline from 2005 (Table 21, Figure 45).

## East of Halifax (4W Eastern Shore)

The 2006 herring gillnet fishery in the Eastern Shore fishing area took place between Sept. 18 and Oct. 172006 with total landings of 3,348t (Figure 46). This is primarily a herring roe fishery with catches reported from three main areas; near Halifax Harbour approaches, southwest of Jeddore Head and south of Ship Harbour. Daily landings were less than 100t/day until Oct. 1, then increased to about 300t/day until Oct. 10. The fishery finished on Oct. 17 after a few days of reduced catches, around 150t/day, from the eastern part of the defined fishing area.

Spawning bed surveys using acoustic equipment were completed in each of the primary fishing areas along the Eastern Shore from Halifax Harbour to near Ship Harbour, N.S. on Sept. 26, Oct. 6 and 15. The total SSB estimated from the three surveys was 51,100 t which was a substantial increase since 2005 (Table 21, Figure 47).

## Glace Bay

There was minimal catch of 85 t in the Glace Bay area in 2006 due to the poor price for herring roe. As a consequence of this the acoustic survey vessel was not calibrated and there was no survey activity.

## Bras d'Or Lakes

The fishery remained closed. No sampling or acoustic surveys were undertaken in the Bras d'Or lakes to document the size distribution or abundance of herring.

### 4.2 Outlook and Management Considerations

There was an increase in surveyed acoustic biomass in the Halifax/Eastern Shore areas while the Little Hope area saw a large decline (Table 21, 22). A survey with an acoustic recorder was completed for the first time in the Glace Bay area in 2005 but there was no survey effort in 2006. As indicated for the SW Nova Scotia / Bay of Fundy spawning component, summing of multiple surveys may result in overestimates of SSB due to double counting. However, the majority of surveys of the Coastal Nova Scotia spawning component were undertaken on spatially separated aggregations of fish.

Management of these spawning components using "survey, assess, then fish (<10\%)" protocol is considered useful when the components are considered to be healthy and of sufficient size. The history of the application of this protocol has had some mixed success due to some occasional problems in executing surveys.

Management approaches and recent research efforts have improved knowledge in these three areas (Little Hope/Port Mouton, Halifax/Eastern Shore and Glace Bay), but there has been little increase in knowledge in adjacent areas. Individual spawning groups within this component are considered vulnerable to fishing because of their relatively small size and proximity to shore. As in the past five years, it is recommended that no coastal spawning areas should experience a large effort increase until much more information is available on the state of that spawning group, and there should be no new fisheries developed when there is uncertainty regarding stock composition and degree of mixing.

It has been noted since 1997 that the status of herring in the Bras d'Or Lakes is cause for concern. With no sampling or acoustic surveys conducted in 2006, there is no evidence of any improvement. It is therefore appropriate to reiterate from a biological perspective, that no fishing take place on this spawning component.

## 5) SW NEW BRUNSWICK MIGRANT JUVENILES

The southwest New Brunswick weir and shutoff fisheries have relied, for over a century, on the aggregation of large numbers of juvenile herring (ages 1-3) near shore at the mouth of the Bay of Fundy. These fish have been considered to be a mixture of juveniles, dominated by those originating from NAFO Subarea 5 spawning components, and have therefore been excluded from the 4WX quota.

The number and distribution of active weirs have decreased over the past decade, due in part to the conversion of sites to aquaculture, as well as the reduction in landings over the past decade in the Passamaquoddy Bay area (Table 1, 3, 8-9). In 2003 there was a large drop in landings in
the traditional New Brunswick weir and shutoff fishery to 9,000t - the lowest since 1983 - and there was concern expressed for this fishery. In 2004 weir landings increased to 20,600t, the highest since 1994, while in 2005 landings again decreased to 13,055t (Table 3). In 2006 landings remained low with about 14,100t recorded for the New Brunswick weir and shutoff fishery (Figure 48, 49).

Additional analysis was done by weir interaction areas which were first used by Stephenson (1990) to compare weir and aquaculture activities and interactions (Figure 50). Catches by area and month for 2005-2006 showed a shift from Campobello and the Wolves to the Bliss Harbour and Grand Manan areas (Table 23-24). There is a trend of decreasing landings in this fishery with catches below the 10 year average for 4 out of the last 5 years (Table 3, Figure 51).

Preliminary results from tagging studies conducted on weir fish since August 2002 have indicated a link between the fish caught in the weir fishery and those caught in the fall and winter purse seine fishery off Grand Manan (Waters and Clark, 2005). The juvenile fish caught in the purse seine fishery are counted against the 4VWX quota, whilst those caught in the weirs are considered to be of Subarea 5 origin. The recent US management plans (NEFSC 1998, 2004) assumes that all of the juvenile herring from this fishery originate from the US "coastal complex" ( $5 Y+5 Z$ ) which is reported to be at reduced levels of abundance.

The size of herring caught from this fishery was abnormally small throughout the season and impeded markets (Figure 52). In 2006, the size composition indicated that the catch was composed primarily of juvenile fish ( $<23 \mathrm{~cm}$ ) with a substantial proportion ( $47 \%$ ) less than 15 cm , which is considered to be mostly age 1 . While large proportions of age 1 fish have been found in the SW New Brunswick catches in the past, for example $70 \%$ in 1980, these have not translated into strong recruitment in subsequent years (Figure 53).

## 6) 5Z Georges Bank

The activities of midwater trawlers and herring purse seiners on the Canadian portion of Georges Bank (area 5Z) were monitored and there were no reported landings or effort (Table 1).

## Acknowledgements

The authors would like to thank the following for their invaluable contributions to the provision of survey data and other assistance in the preparation of this report: Atlantic Herring Co-Op; Cape Breeze Seafoods; Comeau's Sea Foods Ltd.; Connors Bros. Ltd.; Herring Science Council; Eastern Shore Fishermen's Protective Association; Fundy Weir Fishermen's Association, Glace Bay herring gillnet group; Little Hope Management Committee; Scotia Garden Seafood Inc. and South-West Seiners.

Table 17. An evaluation of 2006 fishery observations for the SW Nova Scotia/Bay of Fundy spawning component progress against biological objectives in the management plan for the fishery.

| Objective | 2006: Observations |
| :--- | :--- |
| Persistence of all spawning <br> components | Spawning not observed on Lurcher. Biomass increases in <br> Scots and Trinity still low. Some spawning near Seal <br> Island. |
| Maintain biomass of each <br> component | All spawning areas had slightly increased biomass <br> estimates from 2005 but are still at historically low levels. <br> Substantial decline from 2004. Scots, Trinity, Lurcher and <br> Seal are at very low biomass. |
| Maintain broad age <br> composition | Proportion of larger (30 cm+) sizes has contracted and is <br> very low. Age composition is assumed to be truncated <br> with an absence of larger fish in the population. Recent <br> increase in abundance of herring in the 23-30cm size <br> range is a positive signal for potential future population <br> growth. |
| Maintain long spawning <br> period | Start and duration of spawning in 2006 for German Bank <br> appeared normal but Scots Bay displayed a midseason <br> gap. |
| Fishing mortality at or below <br> F0.1 | Fishing mortality is likely high and well above F0.1. |
| Maintain spatial and <br> temporal diversity of <br> spawning | Insufficient spawning in some areas. |
| Maintain biomass at <br> moderate to high levels | SSB remains near the lowest recorded level since 1999 <br> from the acoustic surveys. |

Figure 4. Major and minor NAFO unit areas used for sample and catch data aggregation.

Figure 5. Herring fishing ground areas by 10 mile boxes and management lines for NAFO areas, 25 mile offshore line, coastal embayment line and herring area lines.

Figure 6. Annual herring landings [bars] and TAC [solid line] (quota) for the southwest Nova Scotia spawning component (4WX stock).

Figure 7. Annual herring landings by gear component for the southwest Nova Scotia spawning component (4WX stock).

Figure 8. Overall 2005-2006 quota year herring purse seine catches (t) for NAFO areas 4WX (from Statistics Division MARFIS database).

Figure 9. Herring purse seine catches as a proportion of overall landings for selected fishing grounds in the southwest Nova Scotia spawning component from 1997-2006.

Figure 10. 2005 fall fishery herring purse seine catches (t) by month in NAFO areas 4WX from 2005-2006 quota year (from Statistics Division MARFIS database).

Figure 11. 2006 herring purse seine catches (t) by month in NAFO areas 4WX from 2005-2006 quota year (from Statistics Division MARFIS database)

Figure 12. Herring purse seine catches for the Scots Bay area from 2001-2006 with catch totals for the overall area, the middle 'Spawning' area and the inner 'Strata' area which was used as the primary search area in acoustic surveys.

Figure 13. Annual herring purse seine catches for the Scots Bay area from 1987-2006 with duration of fishery in days (start date to end date).

Figure 14. 2001 to 2006 daily purse seine herring catches in tonnes (bars) for Scots Bay with the cumulative total catch (solid line) over the entire fishing season.

Figure 15. Annual herring purse seine catches for the German Bank area from 19852006 with pre-spawning and spawning period catches based on an Aug. 15 start date for the defined spawning period and overall German Bank catches as a proportion of the TAC.

Figure 16. Herring purse seine pre-spawning period catches (May 1 to Aug. 14) for German Bank from 1995-2006 with catch totals for the overall catch area, the middle 'Spawn Box' and the inner 'Strata Box' which was used as the primary search area in acoustic surveys.

Figure 17. Herring purse seine spawning period catches (Aug. 15 to Oct. 31) for German Bank from 1995-2006 with catch totals for the overall catch area, the middle 'Spawn Box' and the inner 'Strata Box' which was used as the primary search area in acoustic surveys.

Figure 18. 1997 to 2006 daily purse seine herring catches in tonnes (bars) for German Bank with the cumulative total catch (solid line) over the defined spawning season from Aug. 15 to Oct. 30.

Figure 19. Trinity Ledge/Spectacle Buoy herring catches for 2006 with overall catch amounts and catch portions within the defined spawning area (TL-Spawning Box) and survey areas (TL-Strata Box).

Figure 20. Daily herring landings for 2006 Trinity Ledge/Spectacle Buoy area with acoustic survey dates highlighted in red (darkened) for nights of Sept. 7, 8, 15 (purse seiner) and $20^{\text {th }}$. Note that an additional survey on Sept. 3 where there were no landings is not shown.

Figure 21. Herring set and drift gillnet catches (t) for 2006 calendar year for NAFO areas 4VWX (data from Statistics Division MARFIS database).

Figure 22. Nova Scotia herring weir catches for the 2006 calendar year.

Figure 23. Purse seine catch (top panel), effort (middle panel) and CPUE (bottom) from 1989 to 2006 annual 4WX herring landings data for the SW Nova Scotia/Bay of Fundy spawning component.

Figure 24. SSB index from acoustic surveys for the SW Nova Scotia / Bay of Fundy spawning component overall area and for the German Bank and Scots Bay areas.

Figure 25. 2005 herring sampling coverage from all sources (number of length frequency samples by 10 mile square).

Figure 26. Historical catch at age (numbers) for the SW Nova Scotia / Bay of Fundy spawning component. Refer to Table 18 for actual numbers represented by symbol size. The value for 1968 at age 2 represents the maximum in the series of 2.389 billion. Several of the stronger year-classes are highlighted including the 1970, 1976, 1983, 1998 and 2001 year-classes (from Power et al, 2006a).

Figure 27. SW Nova Scotia spawning component overall landings (t) and average fish weight in the catch for the period 1965-2006.

Figure 28. Catch at length (\% number) for the 1992 overall SW Nova Scotia / Bay of Fundy herring spawning component.

Figure 29. Catch at length (\% number) for the 2006 overall SW Nova Scotia / Bay of Fundy herring spawning component.

Figure 30. Catch at length (\% number) for the 1999-2006 overall SW Nova Scotia / Bay of Fundy herring spawning component. Open bar is used to designate the 30 cm interval for comparison between years.

Figure 31. Proportions of size groups (\% number) $23-30 \mathrm{~cm}$ and $>30 \mathrm{~cm}$ herring in the catch from the SW Nova Scotia / Bay of Fundy spawning component for 1992 and 19992006.

Figure 32. Fishing mortality (ages 5-8 weighted by population numbers) from a series of VPA's calibrated with the German Bank acoustic index for the Expert Opinion (DFO 2006).

Figure 33. Fishing mortality (ages 5-8 weighted by population numbers) from a series of VPA's calibrated with the German Bank acoustic index for this assessment (Melvin and Power, 2007).

Figure 34. Herring purse seine catches on the offshore Scotian Shelf banks for 2006 with embayment and offshore 25 mile lines shown.

Figure 35. Herring midwater trawl catches on the offshore Scotian Shelf banks for 2006 with embayment and offshore 25 mile lines shown.

Figure 53. Catch at age (\% numbers) for the 1978-2005 SW New Brunswick migrant juvenile herring component.

[^0]:    $\wedge$ Annual landings by purse seiners are defined for the period from October 15 of the preceding year to October 14 of the current year.
    *Adjusted totals includes misreporting adjustments for 1978-84 (Mace 1985) and for 1985-93 (Stephenson 1993, Stephenson et al 1994)
    All landings by other gear types are for the calendar year.
