* This series documents the scientific basis for the evaluation of fisheries resources in Canada. As such, it addresses the issues of the day in the time frames required and the documents it contains are not intended as definitive statements on the subjects addressed but rather as progress reports on ongoing investigations.

* La présente série documente les bases scientifiques des évaluations des ressources halieutiques du Canada. Elle traite des problèmes courants selon les échéanciers dictés. Les documents qu'elle contient ne doivent pas être considérés comme des énoncés définitifs sur les sujets traités, mais plutôt comme des rapports d'étape sur les études en cours.

Research documents are produced in the official language in which they are provided to the Secretariat.

Les documents de recherche sont publiés dans la langue officielle utilisée dans le manuscrit envoyé au Secrétariat.

ABSTRACT

Sentinel enterprises continued to collect catch rate and biological information on inshore 3Ps cod resources in 2006 and 2007. Gillnet catch rates (weekly average number of fish per net) in the most recent years remained low compared to 1996-98 catch rates. Catch rates in small mesh gillnet remained low. Length frequencies of cod caught in small mesh gillnet showed fewer fish at the two size modes (36-44 cm and 52-56 cm) than those caught since 2000. Linetrawl catch rates (weekly average number of fish per 1000 hooks) increased from 2000 and showed an increase in the number of fish at the 44-54 cm size range from 2002 to 2004. In 2005, linetrawl catch rates declined, but increased in 2006 and preliminary results indicate linetrawl catch rates remain high in 2007.

RÉSUMÉ

L'entreprise Sentinel a continué de collecter les données relatives au taux de prise ainsi que les données biologiques concernant les ressources côtières de morue de la subdivision 3P en 2006 et 2007. Les taux de prise au filet maillant (nombre moyen hebdomadaire de poissons par filet) des dernières années sont restés faibles par rapport aux taux de prise de 1996 à 1998. Les taux de prise au moyen des petits filets maillants sont également restés faibles. Selon les fréquences de longueur des morues pêchées au moyen de petits filets maillants, le nombre de poissons des catégories de 36 à 44 cm et de 52 à 56 cm est en baisse par rapport à l'année 2000. Les taux de prise à la palangre (nombre moyen hebdomadaire de poissons par 1 000 hameçons) ont augmenté depuis l'année 2000, de même que le nombre de poissons de la catégorie de 44 à 54 cm, par rapport aux années 2002 à 2004. En 2005, les taux de prise à la palangre ont baissé, avant d'augmenter en 2006. Selon les résultats provisoires, les taux de prise à la palangre sont restés élevés en 2007.

INTRODUCTION

Sentinel survey projects were formally announced by the Minister of Fisheries and Oceans in October 1994. The surveys in the DFO Newfoundland Region are an extension of the index fishermen's project from the Northern Cod Science Project with modifications to allow for science activities achievable only under a fishing moratorium. Sentinel data collection has continued during the index fishery of 1998 and commercial fisheries in 1999 -2005.

The sentinel survey has the following objectives:

1. To develop a catch rate series for use in resource assessments.
2. To incorporate the knowledge of inshore fishers in to the resource assessment process.
3. To describe the temporal-spatial distribution of cod in the inshore area over a number of years through, for example, the use of catch rate information, tagging studies, by-catch information and fishers' observations.
4. To gather length frequencies, sex and maturity data and sample ages for use in resource assessment.
5. To establish a long-term physical oceanographic and environmental monitoring program of the inshore areas.
6. To provide a source of biological material for other researchers. For example, tissue for genetic, physiological and toxicological analyses, cod stomachs for food and feeding studies and by-catch information.

PARTICIPANTS

The primary collectors of data in the sentinel survey are inshore fishers. Through consultation with inshore fishers and fisheries organizations, traditional inshore fishing grounds were identified and mapped, resulting in 16 locations in NAFO Subdiv. 3Ps.

Fishers from communities within the boundaries of the identified coastal areas and who met eligibility criteria were invited to apply to participate in the survey. Where more than one application was received from an area, the project partner conducted a draw or lottery to select the participant. While there was considerable interest in the project in most areas, there were many sites from which only one application was received and others where additional canvassing was required to enlist participants. Selected participants were required to complete a six-week course designed by the Marine Institute of Memorial University in consultation with DFO. Topics covered included scientific sampling methods and equipment, computer use, resource assessment basics and presentation skills.

In order to minimize inter-annual enterprise effects on data collection, participants are expected to remain with the survey over a number of years. It is also expected that most of the sampling activities will continue once commercial fishing operations resume and the sentinel participants will form a core of index fishers.

SITES

Since 1995, participants from 19 communities have taken part in the Sentinel program. The specific location of each site was chosen after consultation between DFO scientists, fishermen and the Fish, Food and Allied Workers Union (FFAW). Site selection was based on the need to survey throughout inshore areas and targeted historical fishing areas and historical gear use patterns. Several sites no longer participate in the survey and in 2003 fourteen enterprises continued to collect information. From 2004 to 2007, thirteen sites continued with the program. In 2006, the enterprise in Francois retired and was replaced by another participant.

SAMPLING STRATEGY

The communities of the enterprises involved in the Sentinel survey, as well as the number of sets completed each year and the total number of weeks allocated, are given in Table 1. Survey activity was lowest in 2003, when several sites were cut from the program due to funding pressures and the number of weeks allocated for the survey was also reduced. The timing of sampling was determined after discussions with fishers but was targeted for seasonally appropriate times based on historical fishing patterns. There was minimal disruption of these time frames in 1999 through 2007 due to the opening of the commercial fishery.

There were no traps involved in Sentinel sampling in 3Ps in 1999, or 2002-07; two traps were used in 2000 and three in 2001. Participants used either baited trawl lines or gillnets for the remaining weeks of the survey. Non-trap sites fished either baited trawls or gillnets for the full survey. While traps were in the water continuously, they were hauled three days per week. Hook and line and gillnet crews fished up to three days per week. Fishing days in the week were selected at the discretion of the crew and depend primarily on weather conditions.

When a cod trap was hauled, the crew estimated how much fish by weight had been caught, removed a random sample for biological sampling and released the remaining catch. Meshed and/or dead, floating fish were retained and brought ashore. Fishers were instructed to release as much live fish as possible.

Hook and line crews fished two tubs of baited linetrawl. Each tub consisted of approximately 500 hooks for a total of 1000 hooks per fishing day. Gillnet crews fished a maximum of six fifty fathom 5½ inch monofilament gillnets. Nets were rigged 2-3 to a fleet and up to three fleets were fished per fishing day. Selected sites fished one 3¼ inch monofilament gillnet tied to one 5½" gillnet one day per week. All fish caught in gillnets and on hooks were landed and measured. If catches exceeded 500 kg per week, the numbers of nets in a fleet were cut back. However, some consideration was given to bottom topography and net performance when reducing the number of nets in a fleet. Similarly, the number of hooks per tub was reduced if landings exceeded 500 kg per week. Other measures were considered if fish are particularly abundant in an area and catches appear to be excessive even with the minimal amounts of gear possible.

Prior to the start of sampling in 1995, a fixed (control) location on the fishing grounds was established for each site and will remain fixed for the duration of the project. Each fishing day, up to half of the gear was set at the control site. When competition with commercial fishers prevented setting at the control site, gear was set as close to the

control grounds as possible. The remainder of the gear (experimental) was set at one or two other locations on the fishing grounds at the discretion of the crew. The location of each fishing set was plotted on a nautical chart. The time of the set and the soak time for the gear were recorded. Other environmental observations were recorded, including wind direction and speed, percent cloud cover, tide conditions, presence of invertebrates (bait) and other fish species in the area, marine mammals, sea birds and any other variables which might have influenced fishing behavior. Selected sites were equipped with a CTD (measuring temperature and salinity at depth). At these locations, casts were conducted in the vicinity of fishing sets each fishing day. CTD locations were fished for subsequent years if possible.

When the gear was retrieved, catches from the control and experimental gear were kept separate and sampled on shore. All fish from gillnet, handline and linetrawl, and a sample of the catch from traps, were measured for length and sex. Otoliths were sampled on a length-stratified basis and stored in manila envelopes with relevant information recorded on the outside. Every other week, selected sites collected a sample of up to 100 frozen fish. These were transported to St. John's for detailed biological sampling. All information was recorded on forms similar to those used by the Port Sampling Section and on DFO Research Vessels. Other biological samples were collected as needed.

DATA PRESENTATION

The data are summarized for all of 3Ps and presented by gear type. Summaries for each enterprise follow, in general, organized from east to west. This paper presents data for gillnet (5½" and 3¼" mesh) and linetrawl. The length frequency plots depict the number of fish at length scaled by total amount of gear fished so that changes in length frequency distribution may be compared across years. Lengths, in 1cm intervals, are from both control and experimental gear, and for gillnet and linetrawl represent every fish measured, as the total catch is measured. Length frequency summaries for NAFO division are shown as an average of the relative length frequencies for each fisher in the division. The second figure on each summary sheet gives catch details broken down by year, including total number of sets (Nhails), number of sets in which no fish were caught (Nzero), and number of fish caught (Nmeas). The CPUE figures show control and experimental catches combined, in number of fish per net or per 1000 hooks by week and are constructed by calculating a daily catch rate for each set and averaging all the CPUEs for all sets in a given week.

RESULTS

For those sites in 3Ps collecting data in 2006 and 2007, plots summarizing Sentinel survey activity since 1995 are presented in Fig. 1-90. Thirteen inshore fishing enterprises representing communities from St. Bride's to Burgeo participated in the 3Ps Sentinel Survey for 2006 and 2007. A total of 327 sets of 5½" gillnet and 61 sets of 3¼" gillnet resulted in total measurements of 3890 fish in 2006. Two hundred and fifty-four sets of linetrawl resulted in 19,470 measurements. Data collection is ongoing in 2007 and data presented for 2007 are current to the end of September.

Figures 1 and 2 update all set locations and catch per unit effort in scaled symbols that were surveyed in 2006. Figures 3 and 4 show set locations and scaled catch per unit effort for those sets completed up until the end of September in 2007. Linetrawl and gillnet are shown separately.

Figures 5 and 6 show the overall average CPUE (catch per unit of effort) for all of 3Ps and by community for 5½" gillnet and linetrawl. Gillnet CPUE is considerably lower in recent years in all communities. Linetrawl also declined from 1996 to 2000 but from 2001 to 2005 overall mean CPUE increased to about 100 fish per 1000 hooks. This increase was due largely to good catches of small fish in Burgeo and Ramea and some special sets on Burgeo Bank. As well, in 2002, the participant in Burgeo could not fish the required weeks in the first quarter due to mechanical failure. These weeks fished in previous years had lower catch rates and moderated the yearly mean CPUE. Catch rates in 2006 were higher than the 2001-04 level, at about 150 fish per 1000 hooks and preliminary data show 2007 catch rates to be at a similar level.

Figures 7-9 give length frequencies scaled by amount of activity for the three gear types used in Sentinel surveys. Five and a half inch gillnet catches declined steadily from 1996 to 2000 and have remained low since then (Fig. 7). Three and a quarter inch gillnet (Fig. 8) also declined during this time with changes in which mode of fish size was dominant in various years. The mode of larger fish (second peak in the frequency) was highest in 1996 and much less prominent from 2000 to 2007. Linetrawl frequencies (Fig. 9) showed fewer large fish from 1999 to 2004 but in 2006 and 2007 larger fish are represented in the frequencies than the previous few years.

The summary data for 3Ps gillnet (5½"), in Fig. 10-36, give an indication of catch rate change since inception of the Sentinel Survey in 1995. Gillnets show the narrowest range of selectivity of Sentinel survey gears, targeting fish in the 50 cm to 80 cm range. In general, catch rates from 5½" gillnets were lowest from 2001 to 2006, considerably lower than the best catch rates seen in 1996. Most sites in 2007 had low catch rates similar to those of recent years.

Small mesh gillnets (3¼") have been used in 3Ps since 1995 in order to get information on smaller size ranges of fish. Figures 37-57 summarize the results. One 3¼" gillnet (35 fathoms) was fished in combination with one 5½" Gillnet (50 fathoms) primarily on experimental sites. A strong bimodal peak in length frequency distribution results from this mesh size as the gear selects two size ranges of fish. The first and strongest peak, in most cases, is between 35 cm and 47 cm. Fish in this size range are meshed while the larger fish (52 cm to 65 cm) are caught by the lips and generally entangle as they twist around.

Overall mean catch rates in the small mesh gear have been lower since 2000 than those seen in 1996 through 1999. The last strong peak in the 35 cm to 47 cm range was in 1999 and in the second size range (52 cm to 65 cm), very few fish have been caught in this gear since 1999.

Figures 58-90 summarize the data from the linetrawl portion of the 3Ps Sentinel Survey. Linetrawl shows a much wider selectivity curve than gillnet and catches mainly fish between 29 cm and 83 cm. Linetrawl catch per unit effort declined consistently from 1995 through 2000. From 2000 to 2005, catches increased slightly and were composed of smaller fish. Catch rates were higher in 2006 than those in 2001-05, and preliminary results indicate 2007 catch rates remain high. Length frequencies in 2006 and 2007 included slightly larger fish compared to 2003.
