This series documents the scientific basis for the evaluation of aquatic resources and ecosystems in Canada. As such, it addresses the issues of the day in the time frames required and the documents it contains are not intended as definitive statements on the subjects addressed but rather as progress reports on ongoing investigations.

La présente série documente les fondements scientifiques des évaluations des ressources et des écosystèmes aquatiques du Canada. Elle traite des problèmes courants selon les échéanciers dictés. Les documents qu'elle contient ne doivent pas être considérés comme des énoncés définitifs sur les sujets traités, mais plutôt comme des rapports d'étape sur les études en cours.

Research documents are produced in the official language in which they are provided to the Secretariat.

This document is available on the Internet at: Ce document est disponible sur l'Internet à:

Cameron, P., G. Chaput, and P. Mallet. 2009. Information on Atlantic salmon (Salmo salar) from Salmon Fishing Area 15 (Gulf New Brunswick) of relevance to the development of the COSEWIC status report. DFO Can. Sci. Adv. Secr. Res. Doc. 2009/078. iv + 40 p.

#### Abstract

This document presents information on Atlantic salmon (Salmo salar) from Salmon Fishing Area (SFA) 15 (northern New Brunswick in DFO Gulf Region) of relevance to the development of the status report by the Committee on the Status of Endangered Wildlife in Canada (COSEWIC). There are 15 recognized Atlantic salmon rivers in this area of which the Restigouche River is the largest river. Data are presented and interpreted relative to the following: biological characteristics, stocking of fish, area of occupancy based on juvenile surveys, indicators of adult abundance for monitored rivers, freshwater production based on juvenile surveys and smolt production, and factors which may be constraining Atlantic salmon abundance. For the rivers in this area, the indices of adult abundance suggest that there were more salmon in the mid to late 1980s than there have been in the past 15 years. As a result of changes in fisheries management, spawning escapement has increased from the 1970s and early 1980s resulting in increased abundance of juvenile salmon. The principal threats are: habitat alteration including habitat fragmentation due to non compliant culverts, hydroelectric power generation and cumulative effect of ecosystem changes.

#### Abstract

\section*{RÉSUMÉ}

Le présent document donne des renseignements sur le saumon de l'Atlantique (Salmo salar) de la zone de pêche du saumon (ZPS) 15 (nord du Nouveau-Brunswick dans la région du golfe du MPO) en vue de la préparation du rapport de situation par le Comité sur la situation des espèces en péril au Canada (COSEPAC). Cette région comporte 15 rivières à saumon, dont la plus importante est la rivière Restigouche. Les données présentées et interprétées se rapportent aux éléments suivants: caractéristiques biologiques, stock de poissons, superficie occupée en fonction des inventaires des juvéniles, indicateurs de l'abondance des adultes dans les rivières étudiées, production en eau douce en fonction des inventaires des juvéniles et de la production de saumoneaux et facteurs nuisant à l'abondance du saumon de l'Atlantique. Les indices d'abondance des géniteurs dans les rivières de cette région suggèrent que la population de saumon était plus abondante du milieu à la fin des années 1980, que dans les 15 dernières années. Les changements apportés à la gestion des pêches dans les années 1970 jusqu'au début des années 1980 ont entraîné une augmentation du nombre d'échappées des géniteurs, ce qui a causé une hausse d'abondance de saumons juvéniles. Les principales menaces sont les suivantes: altération de l'habitat, notamment la fragmentation due à l'utilisation d'aqueducs non conformes, les installations hydroélectriques et l'effet cumulatif des modifications de l'écosystème.

## INTRODUCTION

This document presents information on Atlantic salmon (Salmo salar) from Salmon Fishing Area (SFA) 15 of relevance to the development of the status report by the Committee on the Status of Endangered Wildlife in Canada (COSEWIC). SFA 15 is located in northern New Brunswick within the DFO Gulf administrative region. There are 32 potential Atlantic salmon rivers in this area, of which 15 have freshwater habitat areas quantified (Table 1; Fig. 1). The Restigouche River is the largest river in the area (Table 1; Fig. 1). The Matapedia River, a major tributary in the lower portion of the Restigouche, is assessed separately by the province of Québec. Most of the other rivers are comparatively small with fresh water habitat areas of less than one million $\mathrm{m}^{2}$ (Table 1). A number of smaller rivers in this SFA are not recognized as Atlantic salmon rivers but they may have small runs of Atlantic salmon which are not exploited (Table 1).

The conservation limit reference point for the Restigouche River watershed is an egg deposition rate of 1.67 eggs per productive habitat unit ( $\mathrm{m}^{2}$ ) that will provide maximum sustainable yield of adult salmon. This value is the same reference level used by the province of Québec for managing Atlantic salmon (Caron et al. 1999). Habitat area for juvenile production has recently been updated through interpretation of aerial photos. The province of Québec has evaluated the habitat value of the main stem of the Restigouche River as well as the Matapedia and Patapedia rivers using the habitat characteristics and weighting described by Caron et al. (1999). Habitat area for the Restigouche River (excluding Matapedia) totals 21.62 million $\mathrm{m}^{2}$ with an additional habitat area for the Matapedia River of 6.81 million $\mathrm{m}^{2}$ of wetted area equivalent to 5.12 million $\mathrm{m}^{2}$ of productive habitat units. At an egg deposition rate of 1.67 eggs per $\mathrm{m}^{2}$ (deposition rate for the rivers of the province of Québec), conservation requirements in terms of eggs are 44.66 million eggs, equivalent to 7,000 large salmon (at an average of 6,400 eggs per large salmon). This value is $58 \%$ of the conservation requirement previously reported for the Restigouche River (12,042 large salmon; Randall 1984).

For the other rivers in this area, the default conservation limit egg deposition rate of 2.4 eggs per $\mathrm{m}^{2}$ is used and applied to estimates of wetted area (Table 1). Egg requirements to 11 of these 14 other rivers are less than 1.5 million eggs or roughly less than 250 large salmon.

## BIOLOGICAL CHARACTERISTICS

Smolt age varies from 90\% two-year old smolts in Nepisiguit River (Mowbray and Locke 1998) to $70 \%$ three-year old smolts in the Restigouche River (Tables 2 and 3). The proportion of fouryear old smolts in the Restigouche River has decreased from just under 10\% for 1972 to 1981 (Pickard 1983) to 4\% for the last five years (Chaput et al. 2004).

Small salmon (< 63 cm fork length) are almost exclusively males, and usually comprise less than $50 \%$ of the returns to these rivers. Large salmon ( $>=63 \mathrm{~cm}$ fork length) include two-seawinter (2SW) and three-sea-winter (3SW) maiden spawners, as well as repeat spawners. Four-sea-winter (4SW) maiden salmon have been interpreted from scales collected on salmon from the Restigouche River (Peppar and Pickard 1975; Pickard 1983) and both 4SW and one sample of a five-sea-winter (5SW) maiden salmon were reported from the Nepisiguit River (Mowbray and Locke 1998). The large salmon group are most often greater than $70 \%$ female (Tables 2, $3)$.

Adult salmon in samples from the Restigouche River range in length from about 48 cm to over 120 cm (Fig. 2). By sea age history, one-sea-winter (1SW) salmon have an average fork length of $54.3 \mathrm{~cm}(90 \%$ C.I. 49 to 60 cm$)$ and 2 SW salmon have an average fork length of $77 \mathrm{~cm}(90 \%$
C.I. 69 to 86 cm ) whereas 3SW maiden salmon averaged 93 cm fork length (90\% C.I. 85 to 100 cm ) (Fig. 3). Corresponding predicted mean whole weights of 1SW, 2SW and 3SW salmon are $1.6,4.5$, and 8.8 kg , respectively (Fig. 4). Repeat spawning salmon are also common from the rivers in this SFA with 11 years the oldest age of salmon reported by Pickard (1983). Population monitoring does not allow the calculation of the mean generation time but given the importance of three year old smolts and the abundance of 3SW salmon in the adult returns, mean generation time would be close to 6 years.

Egg to fecundity relationship for Restigouche River salmon has been published by Randall (1989). Large salmon (sexes combined) have a fecundity of about 6,400 eggs per fish.

Most salmon return to the Restigouche prior to September 1 with the first bright salmon in the river by mid to late May. Salmon continue to ascend to the spawning areas into October. Salmon are counted through the Jacquet River and Nepisiguit River counting facilities into late October.

Salmon from rivers in SFA 15 undertake long oceanic migrations as shown by recoveries of tagged salmon from these rivers at West Greenland. Salmon tagged as smolts from the Restigouche River have been intercepted at West Greenland in recent years.

## INFORMATION TO SUPPORT PROPOSALS OF DESIGNATABLE UNITS

Stocking of several rivers of SFA 15 with Atlantic salmon of various life stages has occurred since the government of the day established a fish culture facility on the Restigouche River in 1874 (Table 4). The Restigouche facility was operated by the government of Canada at subsequent locations in Deeside, Flatlands and Charlo in New Brunswick until it was divested to a private "not for profit" organization in 1998. This non-profit organization has continued to operate the Charlo hatchery and conduct similar stocking programs as the previous operator. A subsidiary hatchery facility also was established by the federal government on the Nepisiguit River in 1914 and operated for some years.

An examination of early reports indicates that most stocking occurred at the early life stages of fry, advanced fry and fingerlings. The reports also indicate that eyed Atlantic salmon eggs were routinely transferred from one government hatchery facility to another. For example it was common for eggs of Chaleur Bay and Restigouche origin to be transferred to hatcheries located at Grand Falls and Florenceville on the Saint John River system for grow out and stocking. Similarly the reports indicate that eyed eggs of Miramichi origin were transferred to the Restigouche hatchery for grow out and stocking. These records also indicate that the majority of broodfish were of early run, captured near the New Brunswick shore of the Chaleur Bay and purchased from the commercial fisherman of the district and held and spawned at the government owned New Mills holding pond which had been constructed prior to 1919 (Department of Fisheries, Annual Report on Fish Culture 1937). Broodfish were also captured from the Restigouche River and held in the river in floating cages called pontoons prior to spawning from the early 1940's until the government holding pond was constructed in the early 1960's at Hailes Brook adjacent to the Restigouche River. In recent years, 1980 to present, discrete tributary/river stocks were captured by various methods and the subsequent progeny utilized in area salmon enhancement programs.

Hatchery stocking was especially important in the Nepisiguit River with modest stocking programs in the Restigouche River. An active stocking program has been carried out in the Nepisiguit River for the past three decades, initially to restore the population following a spill of mining waste and overfishing, and subsequently for enhancement purposes (Locke 1998).

Stocking still occurs in the Nepisiguit and Restigouche rivers. Returns to the Restigouche River from stocking programs are considered to be less than $1 \%$ of total returns. Hatchery-origin salmon have represented important proportions of the returns to the Nepisiguit River, as high as $75 \%$ of both small and large salmon (Locke et al. 1994) but the hatchery contribution to this river is much reduced in recent years (Chaput et al. 2006).

## AREA OF OCCUPANCY

To confirm the area of occupancy of Atlantic salmon, 196 sites in 32 rivers of SFA 15 were surveyed by electrofishing for the presence of juvenile Atlantic salmon in 2008 (Fig. 5). Most of the sites were sampled by DFO Science teams but crews from the Nepisiguit Salmon Association sampled six of the rivers. A river is defined as emptying into an estuary or ocean.

Juvenile salmon are distributed throughout SFA 15. Juveniles were not captured in 13 of these rivers (at 34 of 196 sites) (Table 1; Fig. 5). Most of the rivers without salmon juveniles were very small rivers and in many cases, absence of juveniles was due to the presence of natural obstructions such as waterfalls and beaver dams, or the streams are too small for ascension of adult salmon. In one river, Little River (near Bathurst), salmon cannot survive due to toxic conditions (see Threats section).

In many rivers surveyed, two or three cohorts (fry, small parr, large parr) were captured indicating that there had been multiple years of spawning success (Fig. 5).

Long term juvenile abundance surveys completed on Restigouche (New Brunswick) provide an indication of the temporal changes in juvenile salmon presence and abundance, from 1972 to 2008. In the Restigouche River, there has been varying levels of site occupancy by salmon fry with no trend in the proportion of sites sampled which had densities $>1.0$ fish per $100 \mathrm{~m}^{2}$ (Fig. 6 ). There was a significant increasing trend in the proportion of sites which had large parr (age2+ years) at densities greater than 1 fish per $100 \mathrm{~m}^{2}$ (Fig. 6).

## POPULATION SIZE, STATUS AND TRENDS

## Information sources sought/considered

Information on adult salmon abundance comes primarily from angling catches and effort (Table 5). End of season spawner counts have been conducted in some years on the Restigouche River and counts of salmon to a headwater tributary are available for two tributaries of the Restigouche River (Table 6; details in Chaput et al. 2000). A counting barrier on the Jacquet River near the head of tide provides incomplete counts of adults in most years (Table 7). A counting fence has been operated on the Nepisiguit River over the past three decades but installation dates, operational details and washouts have comprised the completeness of the data (Locke et al. 1994; Locke et al. 1997a,b). Juvenile surveys have been conducted annually in the Restigouche River since 1972 (Tables 8 - 10) and abundance indices of juveniles are available for some years from the Jacquet River and the Nepisiguit River. Smolt assessment programs began in 2002 to assess the production and characteristics of smolts from tributaries and from the Restigouche River overall (Chaput et al. 2004).

Abundance and trends are evaluated relative to the recent 16 years, 1993 to 2008. This time period has been chosen because it roughly represents 3 generations and also corresponds to the years since the moratorium on salmon commercial fishing in insular Newfoundland.

Abundances are also put in context of the longer time period when available. Trend in an abundance index ( $\operatorname{Ln}(\operatorname{Index})$ ) is characterized as the instantaneous rate of change ( $Z$ ) over the period 1993 to 2008. Abundance of the 16 year period is expressed as the percent change using $100 *\left(\exp ^{2^{* 16}}-1\right)$.

## Abundance and recent trends

Abundance of adult salmon in the Restigouche River is inferred from angling catches, counts at headwater barriers, and when possible from end of year spawner counts by snorkeling (Table 2; Chaput et al. 2000).

Counts at the two headwater barriers indicate a $50 \%$ decline in abundance in the Northwest Upsalquitch River tributary whereas at the Causapscal River barrier (tributary of the Matapedia) there has been a slight increase over the same period (Table 5; Fig. 7).

Catch per unit effort indices from the recreational fishery suggest an increase for small salmon but a slight decrease for large salmon from the Matapedia tributary for the period 1993 to 2008 (Fig. 8). On average, over 7,000 salmon are angled annually in the Restigouche River (Table 5; Fig.9).

## Other rivers

Over the last two decades, assessment data have also been collected from the Jacquet River and the Nepisiguit River (Table 3). Counts of salmon at a protection barrier near the head of tide on the Jacquet River have frequently been incomplete due to washouts or late installations (Table 7). Adult abundance in the Jacquet River has exceeded the conservation requirement at the start of the time series but in recent years, its status relative to conservation is unknown due to frequent washouts, especially in the fall (Fig.10).

The status of the Nepisiguit River has been uncertain. Estimates of returns and escapements based on fence counts which are generally incomplete indicated that conservation requirements had been achieved in only 2 of 15 years when the stock was assessed (1982 to 1996) (Locke et al. 1997a,b) but estimates based on redd counts in late fall collected by the Nepisiguit Salmon Association indicated that spawning escapement had been around the conservation requirements since 1994 (DFO 2001).

## Freshwater production

Juvenile abundance in the Restigouche River has been monitored annually since 1972. Densities of fry, small parr and large parr all increased post-1984 and remain at high levels (Fig. 11). Fry abundance since 1993 shows a slight decrease whereas small parr and large parr show strong increases in density (Tables 8-10; Fig.11). All sites sampled have become and remain occupied by juveniles with the exception of some small streams which are prone to periodic blockages to spawners by beaver dams. The Matapedia River time series is shorter, starting in 2000, and densities of juveniles are at comparable levels to those of the Restigouche (NB) sites. The water levels in 2008 were unusually high throughout the summer and fall. Results from juvenile salmon surveys in 2008, which showed decreased abundance of all age classes, could be biased due to difficult sampling conditions (extremely high water) rather than an indicator of actual lower abundance.

Smolt production in the Kedgwick River has varied between 1.9 and 3.8 smolts per $100 \mathrm{~m}^{2}$ during 2003 to 2008 whereas production from the Restigouche River overall has varied from 1.4 to 4.1 smolts per $100 \mathrm{~m}^{2}$ ( 400 thousand to 1.1 million smolts) (Table 11). Based on a rough estimate of adult returns to the Restigouche during 1999 to 2003, the smolt production rate is in the order of 50 smolts per large salmon return.

## Other rivers

Salmon fry densities in the Nepisiguit River have increased since the 1980s whereas parr abundance has declined (Fig.12). Juvenile abundances in the Jacquet River are at comparable levels to those of the Restigouche River (Fig.13).

There are no measures of marine return rates for any rivers in this area.

## STATUS

A number of qualitative indicators have been used to infer whether conservation requirements were met. Based on the requirement of 7,000 large salmon and an assumed catch rate of $30 \%$ in the angling fishery, conservation would have been met in 13 of 16 years since 1992 (Table 2). In the Matapedia River, conservation has been achieved every year since 1994 (Table 2). Spawning escapements above conservation are consistent with the sustained high densities of juveniles in the Restigouche River.

In all these rivers, the indices of adult abundance suggest that there were more salmon in the mid to late 1980s than there have been in the past 15 years. As a result of changes in fisheries management, particularly the closure of the Maritime provinces and Quebec commercial fisheries and the mandatory catch and release measures in the angling fishery since 1984, spawning escapement has increased which has resulted in increased abundance of juvenile salmon.

## Estimates of total abundance of salmon in SFA 15

Estimates of total abundance (returns and spawners) of adult salmon in SFA 15 are derived from indicators in the Restigouche River, the major river in this area. The returns and spawners are estimated for the Restigouche River, exclusive of returns to the Matapedia River which are included in Quebec zone Q1.

The Restigouche River stock assessment is based on angling catch with assumed exploitation rates between $30 \%$ (min.) and $50 \%$ (max) with estuary catches added to the estimates of returns. In 2001 to 2008, no corrections to returns for estuary catches were made.

Return and spawner estimates for SFA 15 are based on Restigouche River data, scaled up for SFA 15 based on the ratio of total SFA 15 to Restigouche River angling catches. The minimum and maximum return and spawner estimates are derived from the minimum and maximum ratios of angling catch in all of SFA15 relative to angling catch in Restigouche (New Brunswick) ( $\mathrm{min}=$ 1.117; $\max =1.465$ ) (Tables 12, 13).

Harvests represented retained angling catch plus 6\% catch and release mortality for released fish. For the purposes of developing catch advice for the high seas fisheries, estimates of 2SW returns and spawners are derived using the proportion of 2 SW in large salmon, based on aged
scale samples from angling, trapnets, and broodstock. No scale samples analysis was available for 1970, 1971, 1995, and 1996 to 2008 and the mean value of 0.65 is used.

## Values for 2007 were updated and values for 2008 are preliminary.

Estimated total abundance in SFA 15 of small salmon has increased by $44 \%$ and for large salmon by $18 \%$ over the past 16 years (Fig. 14). There is a very large variability in estimates of small salmon returns which are driven by the variations in small salmon angling catches reported from the Restigouche River. Although large salmon abundance is estimated to have increased over the past 16 years, the average abundance over that period (about 6,000 fish) is only $60 \%$ of the estimated abundance over the previous period 1970 to 1992 (Fig. 14). This contrasts with the small salmon abundance estimate of over 10,000 fish over the recent 16 years, 20\% higher than the mean value estimated for the period 1970 to 1992 (Fig. 14).

The abundance of fry does not correspond to the increased adult abundance estimated from angling catches over the past 16 years. The fry abundance index (in year i) would be expected to correspond to the adult spawner estimate of the previous year (year i-1) so the overall estimate of adult abundance for SFA 15 should be interpreted with caution.

## THREATS

In the context of the identification and management for species at risk, a threat, is 'an activity or process (both natural and anthropogenic) that has caused, is causing, or may cause harm, death, or behavioral changes to a species at risk or the destruction, degradation, and/or impairment of its habitat to the extent that population-level effects occur' (Environment Canada 2006). In essence, it is an activity that imposes a stress on a species at risk population which contributes to or perpetuates its decline, or limits its recovery. In the case of Atlantic salmon, the elevated marine mortality and declining returns in recent years are stress caused by unknown ( but hypothesized) threats.

A semi-quantitative assessment of the impact of habitat-related threats to salmon is summarized in Table 14. The principal threats are: habitat alteration including habitat fragmentation due to non compliant culverts, hydroelectric power generation including dams and reservoir on the Nepisiguit and cumulative effect of ecosystem changes (DFO and MNRF In prep b.). These threats represent a loss of 5 to $30 \%$ of spawners. All other threats represent less than $5 \%$ of spawners lost. Many of these activities can be regulated under various Sections of the Fisheries Act.

Cairns (2001) presents and describes 62 hypotheses which may explain the decline in abundance of Atlantic salmon. Any or all of the factors described may be acting to constrain present abundance of Atlantic salmon in the Gulf rivers. A few of these factors are discussed below.

## Fisheries

Losses of large salmon from fisheries are considered low, restricted to First Nations fisheries and from incidental mortalities associated with catch and release fisheries. Exploitation on egg bearing females is low to moderate (Table 14). Although salmon from SFA 15 rivers continue to be intercepted in the West Greenland fishery, the rate of exploitation is presumed to be very low compared to levels during the peak of the fishery in the 1960s to 1980s.

## Disease

There is history of outbreaks of the fish disease furunculosis, caused by the bacterium Aeromonas salmonicida. Mortalities on salmon in the Restigouche River were most important in the 1970s when hundreds of fish were reported dead during warm and low water events. Since then, annual mortalities have declined despite the confirmed presence of furunculosis in some diagnosed fish.

## Land Use

Forestry, agriculture, and rural development all impact in various ways the fresh water habitat of Atlantic salmon. A restocking program was initiated in the Nepisiguit River following a spill of mining waste.

The Little River (Bathurst) is perpetually toxic to salmon as the stream is heavily polluted by base metal mining effluents.

## Fish passage

Several rivers in this area have natural impassable falls at varying distances from the ocean, limiting access to salmon: South Charlo River, Millstream, Tetagouche River, Nepisiguit River.

There are a few rivers and tributaries with water control structures which impede the migration of Atlantic salmon. These are located at the mouth of the Eel River and the Charlo River approximately five kilometers upstream from the mouth. Dewatering of juvenile rearing areas during low flow conditions happens frequently in a short portion of the Charlo River.

Table 11. Smolt production from Restigouche and Kedgwick rivers 2003 to 2008. Weight $(\mathrm{g})$ is the predicted mean weight for a smolt measuring 130 mm . Smolt run size estimates for Kedgwick River in 2005 are minimum value due to high water conditions.

Table 12. Data and estimation of total returns and spawners of large salmon to SFA 15. Midpoints (assuming 40\% exploitation rate in the angling fishery of the Restigouche River) are shown.

Table 14. Summary of threats to, and rating of effects on recovery and/ or persistence of Atlantic salmon in SFA 15, Northern NB (DFO and MNRF. In prep).

| Potential sources of mortality /harm Permitted and un-permitted activities | Source (with examples) | Proportion of salmon affected LOW < 5\%, <br> MEDIUM 5\% to 30\%, HIGH > 30\%, <br> UNCERTAIN | Causel Time Frame <br> Historic (H) <br> Current (C) <br> Potential (P) | Effect on Population <br> (LOW < 5\% spawner loss, MEDIUM 5\% to 30\% spawner loss, HIGH > 30\% spawner loss, UNCERTAIN) | Management Alternatives/ Mitigation (relative to existing actions) |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Directed Salmon Fishing | Aboriginal | Low | C | Low | Control harvest through agreements between DFO and First Nations |
|  | Recreational: retention \& release | Low | C | Low -1SW retention only | Encourage the use of catch and release measures |
|  | Commercial (domestic) | Not Applicable - all commercial fisheries closed |  |  |  |
|  | High Seas (West Greenland / St. Pierre Miquelon) | Low | H C | Low | Reductions in internal use fisheries in those areas |
|  | Illegal (poaching) | Low | C | Low - increased enforcement in conjunction with DFO and provincial enforcement officers; increased stewardship initiatives with local groups; changed enforcement strategies for more targeted efforts | Continue use of compliance monitors on selected watersheds, including Aboriginal guardians |
|  | CUMULATIVE EFFECT | LOW- MEDIUM | C | LOW - MEDIUM |  |

Table 14 (continued).

| Potential sources of mortality /harm Permitted and un-permitted activities | Source <br> (with examples) | Proportion of salmon affected LOW < 5\%, MEDIUM 5\% to 30\%, HIGH > 30\%, UNCERTAIN | Causel Time Frame Historic (H) <br> Current (C) Potential (P) | Effect on Population <br> (LOW < 5\% spawner loss, MEDIUM 5\% to 30\% spawner loss, HIGH > 30\% spawner loss, UNCERTAIN) | Management Alternatives/ Mitigation (relative to existing actions) |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Bycatch of Salmon in Fisheries for Other Species | Aboriginal | Low | C | Low- all bycatch mandatory release |  |
|  | Recreational | Low | C | Low- all bycatch mandatory release |  |
|  | Commercial near-shore | Low | C | Low- all bycatch mandatory release |  |
|  | Commercial distant | Low | C | Low | None apparent |
|  | CUMULATIVE EFFECT | LOW |  | LOW | None apparent |
| Salmon Fisheries <br> Impacts on <br> Salmon Habitat | Aboriginal | Low | C | Low | None apparent |
|  | Recreational | Low | C | Low | None apparent |
|  | Commercial | Not Applicable- all commercial fisheries closed |  |  |  |
|  | Illegal | Low | C | Low | None apparent |
|  | CUMULATIVE EFFECT | LOW | C | LOW | None apparent |
| Mortality Associated with Water Use | Power generation at dams \& tidal facilities (turbine mortality, entrainment, stranding) | Low - Medium | H C | Low | Thermal generation stations in Dalhousie and Belledune, NB, must comply with conditions of operating license and sec 22 of the Fisheries Act |

Table 14 (continued).

| Potential sources of mortality /harm Permitted and un-permitted activities | Source (with examples) | Proportion of salmon affected LOW < 5\%, MEDIUM 5\% to 30\%, HIGH > 30\%, UNCERTAIN | Causel Time Frame Historic (H) <br> Current (C) Potential (P) | Effect on Population <br> (LOW < 5\% spawner loss, MEDIUM 5\% to 30\% spawner loss, HIGH > 30\% spawner loss, UNCERTAIN) | Management Alternatives/ Mitigation (relative to existing actions) |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Habitat Alterations | Municipal waste water treatment facilities | Low | HCP | Low - few communities | Ensure current projects and future developments meet standards |
|  | Pulp \& paper mills | Low | H C | Low - pulp and paper mills comply with pulp and paper effluent regulations |  |
|  | Hydroelectric power generation (dams \& reservoirs, tidal power): altered behavior \& ecosystems | Low- Medium | HCP | Low - Medium | Must comply with sec. 22 and 35 of the Fisheries Ac. |
|  | Water extractions | Low | HCP | Low | Must meet regulations in place; monitoring; develop regional guidelines |
|  | Urbanization (altered hydrology) | Low | HCP | Low - only small communities | Project redesign/ existing regulation - monitoring |
|  | Infrastructure (roads/culverts) (fish passage) | Medium | HCP | Medium - many non compliant culverts | More monitoring/ enforcement of existing regulations |
|  | Aquaculture siting | Not Applicable |  |  |  |

Table 14 (continued).

| Potential sources of mortality /harm Permitted and unpermitted activities | Source <br> (with examples) | Proportion of salmon affected LOW < 5\%, <br> MEDIUM 5\% to 30\%, HIGH > 30\%, <br> UNCERTAIN | Causel Time Frame Historic (H) Current (C) Potential (P) | Effect on Population <br> (LOW < 5\% spawner loss, MEDIUM 5\% to 30\% spawner loss, HIGH > 30\% spawner loss, UNCERTAIN) | Management Alternatives/ Mitigation (relative to existing actions) |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Habitat Alterations | Agriculture / Forestry / Mining, etc. | Medium | HCP | Medium - potential mineral processing; past mining/ processing | Enforcement/ monitoring of existing suite of regulations; compensations where required |
|  | Municipal, provincial \& federal dredging | Low | HCP | Low | Follow regulations in place; mitigations and compensations as required; minimize amount |
|  | CUMULATIVE EFFECT | MEDIUM | HCP | MEDIUM | None apparent |
| Shipping, Transport and Noise | Municipal, provincial, federal \& private transport activities (inc. land and water based contaminants/ spills) | Uncertain | HCP | Uncertain | None apparent |
| Fisheries on Prey of Salmon (for ex. capelin, smelt, shrimp) | Commercial, Recreational, Aboriginal fisheries for species $a, b$, c etc. | Uncertain | H C | Uncertain | None apparent |
| Aquaculture (Salmon and other species) | Escapes from fresh water, marine facilities, disease, parasites, competition, effects on behaviour and migration, genetic introgression | Low | HCP | Low | Fish health regulations, Introduction and transfer regulation |
| Fish culture I stocking (noncommercial, including private, NGO, government) | Impacts on effective population size, over representation of families, domestication | Low | HCP | Low | Must comply with Introduction and Transfers guidelines. |

Table 14 (continued).

| Potential sources of mortality /harm Permitted and un-permitted activities | Source <br> (with examples) | Proportion of salmon affected LOW < 5\%, MEDIUM 5\% to 30\%, HIGH > 30\%, UNCERTAIN | Causel Time Frame Historic (H) <br> Current (C) Potential (P) | Effect on Population (LOW < 5\% spawner loss, MEDIUM 5\% to 30\% spawner loss, HIGH > 30\% spawner loss, UNCERTAIN) | Management Alternatives/ Mitigation (relative to existing actions) |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Scientific Research | Government, university, community and Aboriginal groups | Low | C | Low - minimal removals for scientific purposes. | None apparent |
| Military Activities | Field operations, shooting ranges | Not Applicable |  |  |  |
| Air Pollutants | Acid rain | Low | H P | Uncertain | None apparent |

## UN-PERMITTED

| Introductions of <br> non-native / <br> invasive species | Smallmouth bass, chain <br> pickerel, muskellunge, <br> rainbow trout, <br> invertebrates, plants, algae | Uncertain |  | Increase monitoring and <br> enforcement activities |
| :--- | :--- | :--- | :--- | :--- | :--- |
| International <br> High Seas <br> Targeted | Flags of convenience? | Uncertain | Uncertain | Conduct education programs | | None apparent |
| :--- |
| Ecotourism and <br> Recreation |
| Private Co's \& public at <br> large (water crafts, <br> swimming, etc) effects on <br>  <br> survival |

Table 14 (continued).

| Potential sources of mortality /harm Permitted and un-permitted activities | Source <br> (with examples) | Proportion of salmon affected LOW < 5\%, <br> MEDIUM 5\% to 30\%, HIGH > 30\%, <br> UNCERTAIN | Causel Time Frame Historic (H) <br> Current (C) Potential (P) | Effect on Population <br> (LOW < 5\% spawner loss, MEDIUM 5\% to 30\% spawner loss, HIGH > 30\% spawner loss, UNCERTAIN) | Management Alternatives/ Mitigation (relative to existing actions) |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Ecosystem change | Climate change, changes in relative predator / prey abundances, disease | Low - Uncertain | C P | Low - Uncertain; some rivers in this area are moderately impacted by low water levels and warm water temperatures; affect on salmon populations is unknown. | None apparent |
| Fish diseases | Furunculosis | Low | H C | Iow |  |

Figure 1. Rivers within Salmon Fishing Area (SFA) 15 of northern Gulf New Brunswick. Index numbers refer to rivers in Table 1. Index numbers 1a to 1d refer to position of major tributaries of the Restigouche River (Index 1): 1a = Matapedia, 1b = Upsalquitch, 1c = Patapedia, 1d = confluence of Kedgwick and Little Main Restigouche.

Figure 2. Example of size distribution (fork length cm ) for male and female salmon from the Restigouche River. Samples are from the year 2000 from multiple locations within the river.

Figure 3. Fork length (cm) at age defined by sea age and spawning history for Atlantic salmon from the Restigouche River. Bullet is the median, horizontal hatches are interquartile range, vertical bars are $95 \%$ confidence interval range. Number above the plots is the sample size. Sea age histories are interpreted as follows: 1, 2 and 3 corresponding sea age of maiden first time spawners; - $C$ are consecutive second time spawners; -CR are repeat spawners on a third or greater spawning migration which returned to a second spawning as consecutives; -A are alternate second time spawners; -AR are repeat spawners on a third or greater spawning migration which returned to a second spawning as alternates. A consecutive spawner is a fish which returned to the river to spawn within the same year as it left the river in the spring as a kelt. An alternate spawner is a fish which spent more than twelve months at sea before returning to spawn after having left the river in the spring as a kelt.

Figure 4. Weight to length relationship for Atlantic salmon from the Restigouche River. Median, $5^{\text {th }}$ and $95^{\text {th }}$ percentile ranges are shown. Data are from the period 1972 to 1984.

Figure 5. Presence/absence of juvenile Atlantic salmon, by number of cohorts (fry, small parr, large parr) at electrofishing sites in rivers of SFA 15 sampled in 2008.

Figure 6. Proportion of sites sampled annually in Restigouche River (N.B.) containing more than 1.0 juvenile per $100 \mathrm{~m}^{2}$ by age/size group.

Figure 7. Counts of all adult salmon (small and large salmon combined) at the Northwest Upsalquitch Barrier (upper) and Causapscal Barrier (bottom), Restigouche River.

Figure 8. Catch per unit of effort (rod day) of small salmon (upper) and large salmon (lower) from Restigouche River (excluding Matapedia) and Matapedia River.

Figure 9. Angling catch of small and large salmon from Restigouche River (excluding Matapedia) (upper) and Matapedia River (lower).

Figure 10. Counts of salmon at the Jacquet River barrier. Square black symbols show years with incomplete counts due to fence washouts or early removal due to inclement weather.

Figure 11. Juvenile abundance index for fry (upper), small parr (middle) and large parr (lower) for the sites sampled in the Restigouche River (NB waters only, excluding Matapedia)

Figure 12. Juvenile indices of abundance from the Nepisiguit River.

Figure 13. Juvenile indices of abundance from the Jacquet River.

Figure 14. Estimated abundance (returns) of small salmon (upper) and large salmon (lower) to SFA 15, 1970 to 2008. Trend lines are shown for the period 1993 to 2008.
