This series documents the scientific basis for the evaluation of aquatic resources and ecosystems in Canada. As such, it addresses the issues of the day in the time frames required and the documents it contains are not intended as definitive statements on the subjects addressed but rather as progress reports on ongoing investigations.

Research documents are produced in the official language in which they are provided to the Secretariat.

This document is available on the Internet at:

<http://www.dfo-mpo.gc.ca/csas/>

La présente série documente les fondements scientifiques des évaluations des ressources et des écosystèmes aquatiques du Canada. Elle traite des problèmes courants selon les échéanciers dictés. Les documents qu'elle contient ne doivent pas être considérés comme des énoncés définitifs sur les sujets traités, mais plutôt comme des rapports d'étape sur les études en cours.

Les documents de recherche sont publiés dans la langue officielle utilisée dans le manuscrit envoyé au Secrétariat.

Ce document est disponible sur l'Internet à:

ABSTRACT

Data from the Sentinel program in the Newfoundland and Labrador region (NAFO Div. 2J3KL and Subdiv. 3Ps) are summarized and updated with 2007 and 2008 data. Average annual catch rates for 5½ inch gillnet (number of fish per net) in 2008 are the highest in the time series for Div. 2J and 3K, and second highest in Div. 3L. In Subdiv. 3Ps, however, catch rates since 2000 have remained at a much lower level than 1996-97 values. Small mesh gillnet (3¼ inch) catch rates have been more variable and trends are more difficult to discern; probably due to the ability of this gear to catch fish from two distinct size ranges. Linetrawl catch rates (number of fish per 1000 hooks) in Div. 3K and 3L showed trends similar to 5½ inch gillnet until 2005, decreasing from the late 1990s to the early 2000s, and then generally increasing. A drop in Div. 3K catch rates in 2006 was followed by an increase to 2008, which is the second highest catch rate in the series. In 2006, catch rates in Div. 3L dropped from the 2004-05 levels, and remain at about the lowest catch rates for this gear in this Division in 2007-08. In Subdiv. 3Ps, linetrawl catch rates decreased from 1996 to 2000 and then were variable, but generally increased to 2008. There has been no Sentinel linetrawl activity in Div. 2J since 2001.

Spatially and temporally, catch rates were variable from year to year and place to place. Higher catch rates have been most consistent from Happy Adventure to Little Catalina in 5½ inch gillnet, from Wesleyville to Bay de Verde in small mesh gillnet and high catch rates were more spatially widespread in linetrawl.

RÉSUMÉ

Les données du Programme sentinelle dans la région de Terre-Neuve-et-Labrador (division 2J3KL et sous-division 3Ps) ont été récapitulées et mises à jour à partir des données de 2007 et de 2008. En 2008, les taux moyens annuels de prises aux filets maillants de 90 cm (5½ po) (nombre de poissons par filet) sont les plus élevés pour la série chronologique dans les divisions 2J et 3K, et viennent au deuxième rang dans la division 3L. Cependant, dans la sous-division 3Ps, les taux de prises depuis 2000 sont restés à un niveau nettement inférieur aux valeurs de 1996-1997. Les taux de prises au moyen de petits filets maillants (21 cm [3¼ po]) ont varié davantage et il est plus difficile de repérer les tendances, sans doute parce que les dimensions de ces filets permettent de capturer des poissons de deux tailles différentes. Dans les divisions 3K et 3L, les taux de prises à la pêche à la palangre (nombre de poissons par 1 000 hameçons) affichaient, jusqu'en 2005, des tendances semblables à celles des taux de prises aux filets maillants de 90 cm (5½ po), diminuant à partir de la fin des années 1990 jusqu'au début des années 2000, puis augmentant généralement. La baisse des taux de prises enregistrée en 2006 dans la division 3K a été suivie d'une augmentation jusqu'en 2008, année où l'on a enregistré le deuxième taux de prises le plus élevé de la série chronologique. En 2006, les taux de prises dans la division 3L avaient baissé par rapport à ceux de 2004-2005 et, en 2007-2008, ils se situent toujours aux taux de prises les plus bas pour ce genre d'engin de pêche dans la division. Dans la sous-division 3Ps, les taux de prises à la pêche à la palangre avaient diminué entre 1996 et 2000, et ensuite ils ont été variables; cependant, ils ont

généralement augmenté jusqu'en 2008. Dans la division 2J, il n'y a pas eu d'activité de pêche sentinelle à la palangre depuis 2001.

Sur les plans spatial et temporel, les taux de prises ont varié d'une année à l'autre et d'un endroit à l'autre. Les taux de prises plus élevés ont davantage été constants de Happy Adventure à Little Catalina, pour ce qui est des filets maillants de 90 cm (5½ po), et de Wesleyville à Bay de Verde, en ce qui concerne les petits filets maillants. Quant à la pêche à la palangre, les taux de prises élevés étaient plus répandus.

INTRODUCTION

Sentinel Survey projects were formally announced by the Minister of Fisheries and Oceans Canada in October 1994. The Sentinel Surveys in the Newfoundland and Labrador Region of the Department of Fisheries and Oceans (DFO) are an extension of the index fishermen's project from the Northern Cod Science Project Program with modifications to allow for science activities achievable only under a fishing moratorium. Sentinel data collection continued during the commercial/index fisheries that occurred from 1998 to 2002, and in 2006-08.

The Sentinel Survey has the following objectives:

1. To develop a catch rate series for use in resource assessments.
2. To incorporate the knowledge of inshore fish harvesters in the resource assessment process.
3. To describe the temporal-spatial distribution of Atlantic Cod in the inshore area over a number of years through, for example, the use of catch rate information, tagging studies, by-catch information and participant' observations.
4. To gather length frequencies, sex and maturity data and sample ages for use in resource assessment.
5. To establish a long-term physical oceanographic and environmental monitoring program of the inshore areas.
6. To provide a source of biological material for other researchers. For example, tissue for genetic, physiological and toxicological analyses, cod stomachs for food and feeding studies, and by-catch information.

MATERIALS AND METHODS

PARTICIPANTS

The primary collectors of data in the Sentinel Survey are inshore fish harvesters. Through consultation with inshore fisher harvesters and fisheries organizations, traditional inshore fishing grounds have been identified and mapped.

Fish harvesters from communities within the boundaries of the identified coastal areas and who met eligibility criteria were invited to apply to participate in the survey. Where more than one application was received from an area, the project partner conducted a draw or lottery to select the participant. While there was considerable interest in the project in most areas, there were many sites from which only one application was received and others where additional canvassing was required to enlist participants. Selected participants were required to complete a six-week course designed by the Marine Institute of Memorial University, in consultation with DFO. Topics covered included scientific sampling methods and equipment, computer use, resource assessment basics and presentation skills.

In order to minimize inter-annual enterprise effects on data collection, participants are expected to remain with the survey over a number of years. It is also expected that most of the sampling activities will continue once commercial fishing operations resume, and the sentinel participants will form a core of index fish harvesters.

SITES

In 2008, forty-three enterprises participated in Sentinel activities in NAFO Div. 2J3KL (down from 57 to 58 prior to 2004), and thirteen enterprises surveyed in Subdiv. 3Ps. The specific location of each site was chosen after consultation between DFO scientists, fish harvesters, the Fish, Food and Allied Workers Union (FFAW), and the Fogo Island and Petty Harbour Cooperatives (for Fogo Island and Petty Harbour). Site selection was based on the need to survey throughout inshore areas and targeted historical fishing areas and historical gear use patterns.

SAMPLING STRATEGY

Table 1 gives the homeports of participants in the Sentinel Surveys in 1995-2008; showing the number of sets completed in each year and the number of enterprises participating in the survey. The timing of sampling was determined after discussions with fish harvesters but was targeted for seasonally appropriate times based on historical fishing patterns.

Gillnets and linetrawls were used to survey inshore areas in Div. 2J3KL and Subdiv. 3Ps. Cod traps were used to varying degrees from 1998-2002 to sample fish, but are no longer used in the Sentinel Survey. Hand lines were used mostly in conjunction with nets or trawls as a means of determining the presence of Cod for tagging purposes, or when nets were not catching fish. Hand lines were used to sample Cod in several locations and information from this survey was used mainly for biological sampling as catch rate information from hand lining is difficult to interpret.

Hook and line crews fished two tubs of baited linetrawl (approximately 500 hooks per tub) each fishing day. Gillnet crews fished a maximum of six fifty-fathom, 5½ inch monofilament gillnets. Nets were rigged 2-3 to a fleet and up to three fleets were fished per fishing day. In addition, selected sites fished one small mesh gillnet (3¼ inch monofilament) tied to one 5½ inch gillnet at least one day per week. All fish caught in gillnets and on hooks were landed and measured. If catches were too large to sample effectively, the number of nets in a fleet (or number of hooks in the linetrawls) was reduced after consultation with DFO scientists. However, consideration was given to bottom topography and gear performance when decreasing the amount of gear. Other measures were considered if fish were particularly abundant in an area and catches appeared to be excessive; even with minimal amounts of gear.

Prior to the start of the survey in 1995, a fixed (i.e., control) location on the fishing grounds was established for each site, and will remain fixed for the duration of the Sentinel project. On each fishing day, up to half of the gear was set at the control site. The remainder of the gear (i.e., experimental) was set at one or two other locations on the fishing grounds at the discretion of the participants. The location of each fishing set was plotted on a nautical chart. Start time of the set and soak time for the gear were recorded. Environmental observations were also recorded, including wind direction and speed, percent cloud cover, tide conditions; presence of invertebrates and other fish species in the area (e.g., bait), marine mammals, sea birds and any other variables that might have influenced fishing behaviour were also noted. For several years selected sites were equipped with a CTD device which measures water temperature and salinity at depth. At these locations, CTD casts were conducted in the vicinity of fishing sets each fishing day. CTD locations were fished for subsequent years when possible.

When gear was retrieved, catches from control and experimental gear were kept separate and sampled on shore. All fish from gillnet, hand line and linetrawl, and a sample of the catch from traps, were measured for total length and sex. Otoliths were sampled on a fish length-stratified basis and stored in manila envelopes labeled with relevant information. Selected participants collected a sample of up to 100 frozen fish on a biweekly basis for detailed biological sampling at DFO's Northwest Atlantic Fisheries Center. Other biological samples were collected when requested.

RESULTS

Table 2 and Fig. 1 summarize Sentinel activity by gear type and NAFO Division from 1995 to 2008; including the number of sets of gear in each Division (Nhails), the total number of fish caught (Nmeas) and the number of sets with no fish (Nzero). Gillnet (5½ inch) in 3K showed a noticeable decrease in number of fish caught despite greater effort in 2000-02. The number of gillnet sets declined in most divisions in 2003, but has remained relatively stable since then. Linetrawl effort in Div. 3K and 3L and Subdiv. 3Ps declined from 1995 to 99 and, in recent years, was much lower at 40-50 sets compared to the 130-365 sets that were done in the first three years of the survey. Sentinel linetrawl activity in Div. 2J was sporadic, and in recent years, has not been used to survey.

Forty-three inshore fishing enterprises, representing communities from Black Tickle to St. Mary's Bay, participated in the 2J3KL Sentinel Survey in 2008. In 3Ps, 13 enterprises continued to collect information. Each enterprise involved surveyed for 10 weeks in most recent years. Survey timing varied at each location as per traditional fishing seasons.

Figures 2-4 show catch per unit effort (CPUE) in scaled symbols from every set in 2007 and 2008 of 3¼ inch gillnet, 5½ inch gillnet, and linetrawl. Control sites were generally consistent from year to year but shifts in location may have resulted due to weather or tide conditions or competition for sites by commercial activity.

Figure 5 shows overall average CPUE by Division from 1995 to 2008 for the three main gear types used in Sentinel activity. Gillnet (5½ inch) catch rates in Div. 2J3KL declined from 1998 to 2002 and then increased from 2002 to 2008. In Subdiv. 3Ps, catch rates were highest in 1997, declined rapidly to 2000 and have been stable at a lower level since. Small mesh gillnet catch rates were more stable over the time series since 1998, and although it is more difficult to determine trends, a decreasing trend from 1996 to the early 2000s is apparent in Div. 3K and 3L as well as in Subdiv. 3Ps. The gear's ability to catch two distinct size ranges of fish could mask trends in either size group from year to year. Linetrawl catch rates were more variable, with the most obvious trend in Div. 3K, where catch rates declined rapidly from 1997 to 2000 and then increasing to near the series high in 2008. Linetrawl was not used extensively in Div. 3K or 3L (66 sets and 32 sets in 2008, respectively) and has not been used in Div. 2J since 2001. In Subdiv. 3Ps, where linetrawl effort was higher (253 sets in 2008), catch rates decreased from 1996-2000 then gradually increased to 2008.

Figures 6-8 give mean CPUE for gillnet and linetrawl with participants' communities listed beginning in the north, from Labrador, around the coast, to the south coast of the island. Spatially, catch rates were variable from year to year and place to place. Higher catch rates were most consistent from Happy Adventure to Little Catalina in 5½ inch gillnet, from Wesleyville to Bay de Verde in small mesh gillnet, and in linetrawl, high catch rates were more spatially widespread. Catch rates in 5½ inch gillnet were very low in northern areas in many

years and were highest around Bonavista and Little Catalina (Fig. 6). In 2007 and 2008, many locations in Div. 2J3KL had the highest catch rates in the time series, particularly in the more northern areas. In Subdiv. 3Ps, 2007 and 2008 catch rates were among the lowest in the series. Small mesh gillnet (Fig. 7) showed more variability in CPUE from year to year and between locations, with high catch rates in Div. 2J and 3K as well as Subdiv. 3Ps in some years. Catch rates were most consistent from Wesleyville to Petley. Linetrawl was not as widely used in Div. 2J3KL and catch rates were variable (Fig. 8).

Tables 3-7 compare the mean yearly catch rate to the overall mean catch rate for each participant from 1995 to 2008. Changes greater than 10% are highlighted. In 2008, 76% of participants in Div. 2J3KL had 5½ inch gillnet control sites that were similar to, or 10% higher, than the overall mean (83% for experimental sets). No sites in Subdiv. 3Ps showed higher than average catch rates in either control or experimental 5½ inch gillnet. For small mesh gillnet, 42% of participants in Div. 2J3KL had similar or increased catch rates compared to the series mean, while 2 of 5 sites in Subdiv. 3Ps had similar or increased catch rates. The majority of linetrawl sites in Div. 2J3KL showed higher than mean catch rates (10% or higher difference) for both control and experimental sets (8/12 and 6/8, respectively).

Length frequencies are shown in Figs. 21-23 as proportion at length by gear type and NAFO division. The 5½ inch gillnet frequencies (Fig. 21) show the narrowest range of size selectivity (about 50-80 cm). Given the highly selective nature of this gear, frequencies are generally the same shape from year to year, although in Div. 3K, the 1997 and 2008 frequencies seem to show a shift toward larger fish. In Div. 2J, the early years of the survey caught few fish in the 5½ inch gillnet and resulted in frequencies that were less smooth in appearance (Fig. 21, first panel).

Small mesh gillnet (3¼ inch mesh) caught primarily smaller fish (in the 35-48 cm range) but also picked up a second mode of fish in the 50-65 cm range (see Fig. 22). Changes in size distribution were difficult to detect in this gear due to its limited selection pattern.

Linetrawl had the widest range of size selection of the three gear types used in the Sentinel Survey, targeting fish from about 30 cm to 70 cm (Fig. 23). Changes in size distribution of fish were detected in this gear more readily and in Div. 3K and 3L a shift toward larger fish was evident from 2002 to 2008. In Subdiv. 3Ps, there was a shift toward larger fish from 2003 to 2006 and then smaller fish were more evident in 2007 and 2008.

Length frequencies, scaled by amount of gear used, are summarized in Fig. 24.

Figures 9-20 present weekly mean catch rates (number of fish per net or 1000 hooks) by year, Division and gear. Week 23 corresponds to June 1 in most years (week 22 in 2001-02, and 2006-07). Catch rates for Div. 2J3KL were higher in some years in late fall (weeks 44-49) in both mesh sizes of gillnet. Not all participants surveyed during this time of year (10 weeks are allocated to each participant based on traditional fishing times), but those that did generally had better catch rates. This may be due to fish moving into over-wintering areas during late fall. In Subdiv. 3Ps, catch rates in gillnets also tended to be higher later in the season. Linetrawl catch rates in Subdiv. 3Ps were higher in the fall and winter in the early part of the time series, but most years since then show similar catch rates throughout the year.

DISCUSSION

This document summarizes the catch rate trends and length frequency data for Sentinel Surveys in NAFO Div. 2J3KL and Subdiv. 3Ps in 1995-2008. Given the large spatial coverage of the survey and the differences in timing of the survey between locations, relating observations on catch rate to changes in population dynamics of Atlantic Cod requires standardizing the data for time and location effects. These analyses were undertaken and reported in Brattey et. al. (2009) for Div. 2J3KL and in the Science Advisory Report for Subdiv. 3Ps (DFO 2009). In general, trends in the unstandardized data were in agreement with results from the analyses that took time and location into account.

SUMMARY

Spatially, catch rates of Atlantic Cod have been variable from year to year and place to place. Higher catch rates have been most consistent from Happy Adventure to Little Catalina in 5½ inch gillnet, from Wesleyville to Bay de Verde in small mesh gillnet, and in linetrawl, high catch rates were more spatially widespread. In recent years, Sentinel catch rates have been increasing in 5½ inch gillnet in all NAFO areas, and in Div. 3K and 3L, 2008 catch rates were comparable to levels in 1996 to 1998. Small mesh (3¼ inch) gillnet and linetrawl trends in catch rate were less clear, but linetrawl in Div. 3K and Subdiv. 3Ps showed general increases in catch rate since about 2000.
