This series documents the scientific basis for the evaluation of aquatic resources and ecosystems in Canada. As such, it addresses the issues of the day in the time frames required and the documents it contains are not intended as definitive statements on the subjects addressed but rather as progress reports on ongoing investigations.

Research documents are produced in the official language in which they are provided to the Secretariat.

This document is available on the Internet at:

<http://www.dfo-mpo.gc.ca/csas/>

La présente série documente les fondements scientifiques des évaluations des ressources et des écosystèmes aquatiques du Canada. Elle traite des problèmes courants selon les échéanciers dictés. Les documents qu'elle contient ne doivent pas être considérés comme des énoncés définitifs sur les sujets traités, mais plutôt comme des rapports d'étape sur les études en cours.

Les documents de recherche sont publiés dans la langue officielle utilisée dans le manuscrit envoyé au Secrétariat.

Ce document est disponible sur l'Internet à:

## ABSTRACT

To enhance the fisheries research database in Northwest Atlantic Fisheries Organization (NAFO) Subdivision 3Ps, under contract to the Department of Fisheries and Oceans (DFO), the Groundfish Enterprise Allocation Council (GEAC) completed a fall survey in 2007 directed at groundfish, with specific interest in cod, American plaice, witch flounder, and haddock. GEAC had previously completed fall surveys to 3Ps from 1997 to 2005. The 2007 survey represents a new starting point for this information: both a new survey vessel and new fishing gear were employed as well the survey area was expanded. In this analysis, catch statistics, length and age distribution, and stratified random survey analysis estimates of biomass, including age distribution estimates, are presented. The results were presented during the regular zonal stock assessment meetings in St. John's (February 2009).

The largest catches of cod were located at the southern entrance to the Halibut Channel and on the western portion of St. Pierre Bank with a few on the eastern side of the mouth of Placentia Bay. The estimated total number of cod for 3Ps is 18.1 million and the estimated total cod biomass is 13.1 ktonnes. For an estimated 8.7 cod per standard 15 minute tow the greatest numbers are at ages 1 (3 fish per tow) and 3 (2.5 fish). From the cod abundance index at length estimates there are two peaks at lengths 16-22 cm and 34-40 cm.

The largest catches of American plaice were located at the southern entrance to the Halibut Channel. The estimated total number of plaice for 3Ps is 127 million. The estimated total plaice biomass is 22.3 ktonnes though there is large variance and hence uncertainty in the estimates. The total mean number of plaice per tow is 58.3 with about 10 fish each at ages 2, 3, and 4. At ages 5 through 8 there are from 4.5 to 5.4 fish per tow. Lesser numbers are at ages 9 (3.2 fish) and 10 (2 fish). The majority of sampled plaice are in the 12-30 cm range.

Witch catches were located at the southern entrance to the Halibut Channel and also on the western portion of St. Pierre Bank both west of St. Pierre et Miquelon and on the Laurentian Channel slopes. The estimated total number of witch for 3Ps is 34.8 million. The estimated total witch biomass is 7.2 ktonnes. The total mean number per tow is 16.7 with the greatest numbers estimated at ages 5 (2.7 fish per tow), 7 (2.5 fish) and 6 (2.4 fish). Of the sampled witch there is a peak in the length distribution at 33 cm with the majority of samples in the 26-43 cm range.

Haddock were caught in only 7 of the 75 successful survey trip sets. The estimated total number of haddock for 3Ps is 2.8 million and the estimated total haddock biomass is 5.8 ktonnes though there is large uncertainty in these estimates due to the few sets reporting haddock: the within-stratum variance being an important factor as well. Seventy-one percent of the total abundance estimate and 91% of the total biomass estimate are for the 51-100 fathom regime.

---

## RÉSUMÉ

Afin d'améliorer la base de données de recherche sur les pêches pour la sous-division 3Ps de l'Organisation des pêches de l'Atlantique Nord-Ouest (OPANO), le Groundfish Enterprise Allocation Council (GEAC) a effectué, à forfait, pour le ministère des Pêches et des Océans (MPO), un relevé d'automne en 2007 sur le poisson de fond, en mettant l'accent particulièrement sur la morue, la plie canadienne, la plie grise et l'aiglefin. Antérieurement, le GEAC avait effectué des relevés d'automne dans 3Ps, de 1997 à 2005. Le relevé de 2007 représente un nouveau point de départ pour cette série de données : un nouveau navire et de nouveaux engins de pêche ont été utilisés, et la zone couverte par le relevé a été élargie. On présente, dans cette analyse, les statistiques sur les prises, les répartitions selon la longueur et l'âge ainsi que des estimations de la biomasse fondées sur des analyses aléatoires stratifiées des données des relevés, y compris des estimations de la répartition selon l'âge. Les résultats ont été dévoilés au cours des réunions zonales régulières d'évaluation des stocks tenues à St. John's (février 2009).

Les plus importantes prises de morue ont été effectuées à l'entrée sud du chenal Halibut et sur la portion ouest du banc de Saint-Pierre, quoique quelques prises ont été réalisées du côté est de l'entrée de la baie de Plaisance. Le nombre total estimé de morues dans 3Ps est de 18,1 millions, et la biomasse totale estimée de la morue est de 13,1 Kt. Pour une estimation de 8,7 morues par trait standard de 15 minutes, les nombres les plus élevés à l'âge 1 sont de 3 poissons par trait et de 2,5 poissons par trait à l'âge 3. D'après les estimations de l'abondance de la morue fondées sur l'indice selon la longueur, deux crêtes sont présentes pour ce qui est des longueurs, à savoir 16-22 cm et 34-40 cm.

Les plus importantes prises de plies canadiennes ont été réalisées à l'entrée sud du chenal Halibut. Le nombre total estimé de plies dans 3Ps se chiffre à 127 millions d'individus. La biomasse totale estimée de la plie est quant à elle de 22,3 Kt, bien qu'il y ait une importante variance et, par le fait même, une grande incertitude en ce qui concerne les estimations. Le nombre moyen total de plies par trait est de 58,3, avec environ 10 poissons représentant les âges 2, 3 et 4. Aux âges 5 à 8, le nombre de poissons par trait varie de 4,5 à 5,4. Les nombres les moins élevés correspondent aux âges 9 (3,2 poissons) et 10 (2 poissons). La majorité des plies échantillonnées mesurent de 12 à 30 cm.

Les prises de plies grises ont été réalisées à l'entrée sud du chenal Halibut et également dans la portion ouest du banc de Saint-Pierre, à l'ouest de St-Pierre et Miquelon et sur le talus du chenal laurentien. Le nombre total estimé de plies grises dans 3Ps se chiffre à 34,8 millions. La biomasse totale estimée de la plie grise équivaut quant à elle à 7,2 Kt. Le nombre moyen total par trait est de 16,7, les nombres les plus importants estimés correspondant aux âges 5 (2,7 poissons par trait), 7 (2,5 poissons) et 6 (2,4 poissons). Parmi les plies grises échantillonnées, on observe une crête dans la distribution selon la longueur à 33 cm, la majorité des échantillons mesurant de 26 à 43 cm.

On a capturé de l'aiglefin dans seulement 7 des 75 calées réussies dans le cadre des relevés. Le nombre total estimé d'aiglefins dans 3Ps est de 2,8 millions d'individus, et la biomasse totale estimée de l'aiglefin se situe à 5,8 Kt, bien qu'il y ait une grande incertitude entourant ces estimations en raison du faible nombre de calées dans lesquelles on a observé de l'aiglefin. La variance dans la strate est également un facteur important. Soixante et onze pour cent de l'estimation de l'abondance totale et 91 % de l'estimation de la biomasse totale se situent dans la plage de profondeurs allant de 51 à 100 brasses.

---

## INTRODUCTION

To enhance the fisheries research database in NAFO Subdivision 3Ps, under contract to the Department of Fisheries and Oceans (DFO), the Groundfish Enterprise Allocation Council (GEAC) completed a fall survey in 2007 directed at groundfish, with specific interest in cod, American plaice, witch flounder, and haddock. The intent has been to provide survey information in 3Ps to complement current resource assessment activities carried out by the Department of Fisheries and Oceans (DFO). GEAC had previously completed fall surveys to 3Ps from 1997 to 2005<sup>1</sup> (McClintock, 2007). The 2007 survey represents a new starting point for this information: both a new survey vessel and new fishing gear were employed as well the survey area was expanded. GEAC conducted the 2007 survey with scientific guidance from DFO in the design and execution of a stratified random survey and the associated sampling. The data collected during these surveys have been subsequently analysed on behalf of GEAC and for the additional intent of providing this information to DFO, for their databases and their assessment work. The results have been presented during the regular Advisory Process meetings in St. John's<sup>2</sup>.

During the trip, set details and length frequencies were logged in the DFO Fisheries Form System (FFS) and otoliths were collected for subsequent aging. Under contract to GEAC, AMEC Earth & Environmental (AMEC) has taken the data logged using the DFO FFS system, combined with the aged otoliths, created digital data files appropriate for inclusion in the DFO databases, and performed a first analysis of the survey results.

In this paper, catch statistics, length and age distribution, and stratified analysis estimates of abundance and biomass, including age distribution estimates, and interpretation of results, are presented separately for cod, plaice, and witch. A similar analysis without the length or aging information is presented for haddock.

*This research document presents the analysis for each of the four species, one species at a time: cod, plaice, witch, and finally haddock. Following a review of methods and materials and an overview of the survey gear net performance, results are presented as follows:*

*Cod: pages 3-4, Tables 1-4, Figures 7-12.*

*Plaice: pages 4-5, Tables 5-8, Figures 13-17.*

*Witch: pages 5-6, Tables 9-12, Figures 18-22.*

*Haddock: pages 6-7, Tables 13-15, Figure 23.*

## METHODS

A Stratified Random survey was carried out in 3Ps by the *Cape Ballard*, owned by Fishery Products International (FPI). A summary of the trip is presented below.

---

<sup>1</sup> There was no 2006 survey.

<sup>2</sup> The 2007 survey and cod results were presented by the author February 25, 2009 as part of the February 24 - March 6, 2009 Zonal stock assessment of Atlantic cod for NAFO divisions/subdiv. (2J3KL, 3Ps, 3Pn4RS, 4TVn, 4X5Y).

---

## TRIP 7: STRATIFIED RANDOM SURVEY

Trip 7 was carried out from 28 November to 12 December 2007. The *Cape Ballard*, sailed from Marystown for operation in 3Ps, St. Pierre Bank, Halibut Channel, and Green Bank.

Figure 1 shows a map illustrating the location of the strata surveyed. Figure 2 shows the location of the survey sets. The survey area was expanded in 2007 compared with the earlier 1997-2005 surveys to include seven additional strata (783, 781, 782, 779, 780, 716, 714) which were added to five of the six depth regimes that span the survey (e.g., Table 4). The survey was directed at cod, American plaice, witch flounder, and haddock. Set details were collected for all species caught: length, sex, and otolith information were sampled for the cod, plaice, and witch. A total of 130 sets were targeted though six days were lost due to weather. 79 sets were subsequently completed and of these 75 were successful. Four sets where the gear was badly damaged and catch affected were unsuccessful: 18, 34, 71, and 75.

Tows of duration 15 minutes with Campelan 1800 trawl with codend liner were conducted<sup>3</sup> and the tows were commenced once the net reached the bottom.

Performance of the trawl was checked onboard using SCANMAR sensors: bridge display of wingspread and net opening (headline height) was visually monitored and these measurements together with trawl depth and water temperature were noted every five minutes on the written bridge log for most sets. The wingspread, clearance, and opening, and for six sets, doorspread, measurements as well as temperature were logged to computer disk every 5 seconds with the DFO Seatrawl software and typically noted every 5 minutes on the bridge log.

Survey set and catch data were logged using FFS with the length and otolith sampling carried out on board.

Additional details are presented in the trip report (GEAC 2007).

## SHORE-BASED ANALYSIS

The set details and (for cod, plaice, and witch) length frequencies were exported from FFS to create ASCII data files. The age and growth data were keyed in following completion of the otolith aging. Cod, plaice, and witch were all sampled in 1 cm length groupings, and all ratio/percentages of catch measured were applied. As noted, there was no haddock age or length information collected.

## GEAR PERFORMANCE

The digital Seatrawl gear performance data were processed using the AMEC NetPlot Windows software developed for DFO as a Seatrawl data processing, viewing, and editing tool.

Statistics were computed by NetPlot with application of typical range checks: in this instance, wingspread and doorspread in the range [2,100 m], opening in [1,35 m] and

---

<sup>3</sup> The 1997-2005 surveys employed a 30 minute set duration and gear of Engels 96 high lift trawl type with a 135 mm diamond mesh cod end (not lined).

---

clearance in [0,50 m]. Digital data coverage was good with wingspread logged for 64 sets; doorspread logged for 6 sets; opening logged for 64 sets; and clearance logged for 72 sets.

Figure 3 and Figure 4 present the derived net wingspread and opening statistics for each set. The mean +/- one standard deviation are shown. The wingspread ranges from 9.7 to 21.1 m with a mean of 15.6 m and a median of 15.7 m. Opening ranges from 1.4 m to 13.9 m with a mean of 5.6 m and a median of 5.5 m.

Figure 5 presents clearance with means that ranges from 0 to 26.4 m. The mean clearance is 3.5 m and the median is 0.3 m.

Figure 6 presents the mean wingspread versus set depth. Wingspread values range between 10 and 20 m for all but two sets. There is a slight increase in wingspread with depth.

As noted, doorspread was measured for six sets only, numbers 2, 4-6, 8, and 11. The mean doorspread ranges from 37 to 48.5 m. On average the value is 43 m and the median is 42.3 m.

There appears to be good consistency in the net performance measurements. As always, it is essential that net performance should be carefully monitored in any future surveys.

For each species, abundance and biomass were estimated using the DFO stratified analysis STRAP software and applying the French Exclusion Zone around St. Pierre et Miquelon for area calculations. Based on guidance received from DFO (D. Power, Pers. Comm.), a wingspread of 55.25 ft (16.84 m) was used.

## RESULTS: COD

ACON<sup>4</sup> scaled symbol plots of the spatial distribution of cod catch weights are presented in Fig. 7. The largest catches were located at the southern entrance to the Halibut Channel and on the western portion of St. Pierre Bank with a few on the eastern side of the mouth of Placentia Bay.

Table 1 presents a summary of the set details and cod catch numbers and weights for the 75 successful sets. The mean cod catch is 14 fish and the mean catch weight is 10 kg. The total number of cod caught was 1054 in 2007. The total catch weight was 751 kg. The largest catch of 122 cod and weight 199 kg was from set 41 in stratum 318 at a depth of approximately 247 m at the mouth of the Halibut Channel. This location is consistent with those of the largest sets historically (McClintock 2007).

To investigate the numbers and distribution of smaller fish, Figure 8 shows the distribution of cod numbers at age in nine panels for ages 1 to 9+. The majority of fish are at ages 1 and 3, with also good representation at ages 2, 4, and 5. The distributions are in general uniform across the survey area. There are few fish older than 5 years.

---

## COD AGE AND LENGTH COMPOSITION

Figure 9 presents the sampled length composition for the 2007 survey. There are two primary peaks: one for smaller fish from about 13-26 cm, centered at 16 cm, and one from about 27-65 cm centered at 36 cm. For illustration only, since in 2007 both a different vessel and different gear were employed compared with 2005, the 2005 survey sampled length distribution is also shown.

Figure 10 presents the sampled length versus age distribution from the 2007 survey. Lengths ranged from 10 to 114 cm with a mean (and median) of 40 cm. Ages ranged from 1 to 14 years with a mean of 3.2 years and median of 3 years (Fig. 11).

## COD ABUNDANCE AND BIOMASS ESTIMATES

Table 2 presents the STRAP output of estimated abundance and biomass. The estimated total number of cod for 3Ps is 18.1 million (with 95% confidence lower and upper limits of 13.6 and 22.7 million). The mean number of cod per standard 15 minute (0.75 nautical mile) tow is 8.7 (with approximate 95% confidence limits of 3 and 8). The estimated total cod biomass is 13.1 ktonnes (with lower and upper limits of 7.6 and 18.5 ktonnes). The mean catch weight per tow is 6.3 kg.

Table 3 presents the STRAP age composition of numbers per tow, with sexes combined. The total mean number per tow is 8.7 with the greatest numbers estimated at ages 1 (3 fish per tow) and 3 (2.5 fish). Lesser numbers are at ages 2 (1 fish), 4 (0.9 fish), and 5 (0.8 fish).

The abundance and biomass estimates by strata, arranged by depth regime, are presented in Table 4. Of the six depth regimes, 58% of the total abundance estimate and 30% of the total biomass estimate are for the 51-100 fathom regime. Two percent of the total abundance and 4% of the total biomass are for the two regimes greater than 150 fathoms. Twenty-seven percent of the total abundance and 40% of the total biomass are for the two depth regimes less than 50 fathoms.

Figure 12 presents the cod abundance index at length for males, females, and combined sexes. Males and females show similar distributions with two peaks at lengths 16-22 cm and 34-40 cm with abundance indices of about 1 million or just less than this for each centimetre length in these ranges.

## RESULTS: PLAICE

ACON scaled symbol plots of the spatial distribution of American plaice catch weights are presented in Fig. 13. The largest catches were located at the southern entrance to the Halibut Channel. The largest catch was set 28 with 1343 plaice and a set catch weight of 128 kg. The set was located in stratum 323 in a water depth of 156 m at the mouth of the Halibut Channel just south of 46°N. Set 37 recorded the largest set plaice weight of 232 kg (464 fish) in a depth of 152 m a bit to the south of other large set 28. Table 5 presents a summary of the plaice set details and catch numbers and weights. The mean plaice catch for the 75 stratified random sets is 70 fish and the mean catch weight is 11 kg. The total number of plaice caught was 5256 in 2007. The total catch weight was 848 kg.

---

## PLAICE AGE AND LENGTH COMPOSITION

Figure 14 presents the sampled length composition for the 2007 survey. The majority of samples are in the 12-30 cm range. There are fewer large fish and more small fish in the 2007 compared with that seen in the 2005 survey which is shown for illustrative comparison only.

Figure 15 presents the sampled length versus age distribution from the 2007 survey. Lengths ranged from 6 to 64 cm with a mean of 29 cm. Ages ranged from 1 to 18 years with a mean of 6.6 years (Fig. 16).

## PLAICE ABUNDANCE AND BIOMASS ESTIMATES

Table 6 presents the STRAP output of estimated abundance and biomass. The estimated total number of plaice for 3Ps is 127 million (with 95% confidence lower and upper limits of 37 and 217 million). The mean number of plaice per standard 15 minute (0.75 nautical mile) tow is 61 (with limits of 18 and 104). The estimated total plaice biomass is 22.3 ktonnes. There is large variance and hence uncertainty in the estimates. For an alpha value of 5%: the upper 95% limit is 47.7 ktonnes but the lower limit is negative. The estimated mean catch weight per tow is 10.7 kg.

Table 7 presents the STRAP age composition of numbers per tow, with sexes combined. The total mean number per tow is 58.3 with about 10 fish each at ages 2, 3, and 4. At ages 5 through 8 there are from 4.5 to 5.4 fish per tow. Lesser numbers are at ages 9 (3.2 fish) and 10 (1.9 fish).

The abundance and biomass estimates by strata, arranged by depth regime, are presented in Table 8. Of the six depth regimes, 80% of the total abundance estimate and 73% of the total biomass estimate are for the 51-100 fathom regime. Less than 2% of the total abundance and less than 3% of the total biomass are for the two regimes greater than 150 fathoms. 12% of the total abundance and 18% of the total biomass are for the two depth regimes less than 50 fathoms.

Figure 17 presents the plaice abundance index at length for males, females, and combined sexes. Males and females show similar distributions with one peak at 12 cm and a second broader peak between lengths 16-36 cm with abundance indices of about 6 million for each sex for each centimetre length in these ranges.

## RESULTS: WITCH

ACON scaled symbol plots of the spatial distribution of witch flounder catch weights are presented in Fig. 18. The largest catches were located at the southern entrance to the Halibut Channel and also on the western portion of St. Pierre Bank both west of St. Pierre et Miquelon and on the Laurentian Channel slopes.

Table 9 presents a summary of the witch set details and catch numbers and weights. The mean witch catch for the 75 stratified random sets is 16 fish and the mean catch weight is 4 kg. The total number of witch caught was 1175 in 2007. The total catch weight was 295 kg. The largest set was set 42 with 95 fish weighing 42 kg in stratum 707 at a depth

---

of approximately 321 m at the western entrance to the mouth of the Halibut Channel. There were five additional sets of catch weight 20 to 31 kg and 41 to 106 haddock.

### **WITCH AGE AND LENGTH COMPOSITION**

Figure 19 presents the sampled length composition for the 2007 survey. There is a peak in the distribution at 33 cm with the majority of samples in the 26-43 cm range. There are fewer large fish and more small fish in the 2007 compared with that seen in the 2005 survey (which is shown for illustrative comparison only), though not to the extent seen for plaice (Fig. 14).

Figure 20 presents the sampled length versus age distribution from the 2007 survey. Lengths ranged from 6 to 55 cm with a mean of 31 cm. Ages ranged from 0 to 13 years with a mean of 6.6 years (Fig. 21).

### **WITCH ABUNDANCE AND BIOMASS ESTIMATES**

Table 10 presents the STRAP output of estimated abundance and biomass. The estimated total number of witch for 3Ps is 34.8 million (with 95% confidence lower and upper limits of 25.3 and 44.2 million). The mean number of witch per standard 15 minute (0.75 nautical mile) tow is 16.7 fish (with limits of 12.2 and 21.3). The estimated total witch biomass is 7.2 ktonnes (with lower and upper limits of 4.3 and 10.1 ktonnes). The mean catch weight per tow is 3.5 kg.

Table 11 presents the STRAP age composition of numbers per tow, with sexes combined. The total mean number per tow is 16.7 with the greatest numbers estimated at ages 5 (2.7 fish per tow), 7 (2.5 fish) and 6 (2.4 fish). Lesser numbers are at ages 8 (2 fish), 9 (1.7 fish), 4 (1.6 fish), and 3 (1.5 fish).

The abundance and biomass estimates by strata, arranged by depth regime, are presented in Table 12. Of the six depth regimes, 49% of the total abundance estimate and 25% of the total biomass estimate are for the 201-300 fathom regime. 23% of the total abundance and 43% of the total biomass are for the 51-100 fathom regime. There are virtually no witch in depths less than 50 fathoms.

Figure 22 presents the witch abundance index at length for males, females, and combined sexes. Males and females show similar distributions with a broad peak in the length range 26-42 cm with abundance indices of 1-2 million for each sex for each centimeter length in this range. There is a secondary peak at about 18 cm with abundance indices of about 1 million for each centimetre length near this peak.

## **RESULTS: HADDOCK**

ACON scaled symbol plots of the spatial distribution of haddock catch weights are presented in Figure 23. The only catches were located at the southern entrance to the Halibut Channel (four sets of 8 to 41 haddock and set weights 20 to 110 kg, together with one set of 36 haddock weighing 5 kg farther to the west) together with two sets on the northwestern portion of St. Pierre Bank west of St. Pierre et Miquelon (8 and 17 haddock weighing 1 and 11 kg). These sets were all in the depth range of 140 to 247 m.

---

Table 13 presents a summary of the haddock catch set details and catch numbers and weights. The mean haddock catch for the 75 stratified random sets is 1.9 fish and the mean catch weight is 2.8 kg. The total number of haddock caught was 140 in 2007. The total catch weight was 213 kg. The largest catch of 41 cod and weight 110 kg was from set 36 in stratum 319 at a depth of approximately 140 m at the mouth of the Halibut Channel.

## HADDOCK ABUNDANCE AND BIOMASS ESTIMATES

Table 14 presents the STRAP output of estimated abundance and biomass. The estimated total number of haddock for 3Ps is 2.8 million. There is large uncertainty in the estimates for an alpha value of 5%: the upper 95% limit is 7.2 million. The estimated mean catch is 1.4 haddock per standard 15 minute (0.75 nautical mile) tow.

The estimated total haddock biomass is 5.8 ktonnes. Again there is large uncertainty in the estimate due to the few sets (just four stratum 310, 316, 318, and 319) recording any haddock and high variance. The mean catch weight per tow is 2.8 kg with a 95% upper limit of 8.2 and a negative lower limit.

The abundance and biomass estimates by strata, arranged by depth regime, are presented in Table 15. Of the six depth regimes, 71% of the total abundance estimate and 91% of the total biomass estimate are for the 51-100 fathom regime. The only other regime represented is the 101-150 range which comprises 29% of the total abundance and 9% of the total biomass.

## ACKNOWLEDGMENTS

The author thanks Dawn Maddock Parsons, Joanne Morgan, Brian Healey, and Don Power for their kind assistance in review of this document. Some additional assistance of Don Power in STRAP run execution and interpretation is greatly appreciated.

- GEAC, December 17, 2007. "3Ps Cod Survey – 2007. Final Report."
- McClintock, J. 2007. Year nine of the NAFO Subdivision 3Ps Fall GEAC surveys: Catch results for Atlantic cod (*Gadus morhua*), American plaice (*Hippoglossoides platessoides* F.), witch flounder (*Glyptocephalus cynoglossus* L.), and haddock (*Melanogrammus aeglefinus*). DFO Can. Sci. Advis. Sec. Res. Doc. 2007/055. 62p.

**Table 1. Summary of cod catches for stratified random survey, NAFO Subdivision 3Ps, 29 November–12 December 2007**

Cape Ballard Trip 7				Unit	Depth (m)	Set Location	COD	Set Duration (min)	Tow Distance (n.mi.)	COD Mean Weight (kg)
