This series documents the scientific basis for the evaluation of aquatic resources and ecosystems in Canada. As such, it addresses the issues of the day in the time frames required and the documents it contains are not intended as definitive statements on the subjects addressed but rather as progress reports on ongoing investigations.

La présente série documente les fondements scientifiques des évaluations des ressources et des écosystèmes aquatiques du Canada. Elle traite des problèmes courants selon les échéanciers dictés. Les documents qu'elle contient ne doivent pas être considérés comme des énoncés définitifs sur les sujets traités, mais plutôt comme des rapports d'étape sur les études en cours.

Research documents are produced in the official language in which they are provided to the Secretariat.

Les documents de recherche sont publiés dans la langue officielle utilisée dans le manuscrit envoyé au Secrétariat.

Ce document est disponible sur l'Internet à:

Simpson, M.R., Miri, C.M., and Mello, L.G.S. 2012. An assessment of Thorny Skate (Amblyraja radiata Donovan, 1808) in NAFO Subdivision 3Ps and Divisions 3LNO. DFO Can. Sci. Advis. Sec. Res. Doc. 2012/139. iv +38 p.

#### Abstract

Available information on the fishery, management, and biology of Thorny Skate in NAFO Subdivision 3Ps and Divisions 3LNO were reviewed to determine the status of this stock. Based on a continuous distribution and lack of physical barriers between Subdiv. 3Ps and Div. 3LNO, Thorny Skates in Div. 3LNOPs are considered to constitute a single stock. This stock is managed by Canada in Subdiv. 3Ps, and by the Northwest Atlantic Fisheries Organization in the NAFO Regulatory Area (outside Canada's 200-mile limit) of Div. 3LNO. In Subdiv. 3Ps, with the commencement of a Canadian skate-directed fishery in 1994, NAFO-reported landings averaged 1308 tons annually over 1994-2009; which decreased to a 808-t average in 2010-11. In 2005-11, reported landings from Div. 3LNO averaged 5548 tons annually; down from an average of 13064 t for all countries in 1997-2004. Commercially reported landings data do not include discards at sea, and skate landings are never reported by species; except by Canadian Fisheries Observers. At-sea sampling of Canadian commercial catches for skate lengths by Fisheries Observers was limited in 2010, and non-existent in 2011. An Index of Fishing Mortality for Subdiv. 3Ps remained below $8 \%$ since 1996, declined through the late 2000s, and reached its lowest value in 2010-11 (2\%). Fishing Mortality in Div. 3LNO increased from the late 1980s to a peak of 29\% in 1997; then averaged 17\% during 1998-2004. In 2005, this Index reached its lowest value (4\%), and subsequently remained below 8\%. In Subdiv. 3Ps, Canadian Campelen spring research surveys suggest a gradually increasing trend in Thorny Skate biomass over 1996-2012; averaging 31400 tons annually. The Subdiv. 3Ps spring survey abundance index was relatively stable in 1996-2012; fluctuating around 23 million skates. After a declining trend in Div. 3LNO over 1985-95 (Engel spring surveys), Campelen spring survey biomass indices followed a gradually increasing trend; averaging 85500 tons annually. The Div. 3LNO spring abundance index was relatively stable in 1996-2012; fluctuating around 51 million skates. Thorny Skate distribution in Div. 3LNOPs has changed since the 1980s, from a widespread distribution over the Grand Banks in moderate to high concentrations, to a more limited distribution along the southwest edge of the bank in the late 1990s (Div. 3O); Thorny Skate distribution in 2007-12 continued to be concentrated on the southwest boundary of the bank in Div. 3O, in Subdiv. 3Ps, and along the shelf edge of the Grank Banks in Div. 3LN. Length distributions of Thorny Skate sampled in Canadian spring surveys of Subdiv. 3Ps and Div. 3LNO in 1998-2012 indicate that the highest percentage of young-of-the-year skates (520 cm TL) for this period was observed in 2009. The primary purpose of this paper is to provide an update on Thorny Skate stock status in Subdiv. 3Ps for use by fisheries managers in formulating conservation measures for this stock.

## RÉSUMÉ

Les renseignements disponibles sur la pêche, la gestion et la biologie de la raie épineuse dans la sous-division 3Ps et les divisions 3LNO de l'Organisation des pêches de l'Atlantique NordOuest (OPANO) ont fait l'objet d'un examen pour déterminer l'état de ce stock. D'après une répartition continue et l'absence d'obstacles entre la sous-division 3Ps et les divisions 3LNO, on considère que les raies épineuses présentes dans la division 3LNOPs appartiennent à un seul stock. Ce stock est géré par le Canada dans la sous-division 3Ps et l'OPANO dans la zone réglementée par l'OPANO (à l'extérieur de la limite des 200 milles du Canada) des divisions 3LNO. Dans la sous-division 3Ps, avec le début d'une pêche dirigée de la raie du Canada en 1994, les débarquements signalés par l'OPANO se situaient en moyenne à 1308 tonnes par année entre 1994 et 2009, pour ensuite diminuer à une moyenne de 808 tonnes en 2010-2011. Entre 2005 et 2011, les débarquements signalés dans les divisions 3LNO se chiffraient en moyenne à 5548 tonnes annuellement, soit une diminution par rapport à une moyenne de 13064 tonnes pour tous les pays entre 1997 et 2004. Les données sur les débarquements signalés de la pêche commerciale ne comprennent pas les rejets en mer, et les débarquements de raies ne sont jamais déclarés par espèce, sauf dans les données des observateurs des pêches du Canada. L'échantillonnage en mer des prises commerciales canadiennes portant sur la longueur des raies par les observateurs des pêches a été limité en 2010 et inexistant en 2011. L'indice de la mortalité par la pêche de la sous-division 3Ps est demeuré inférieur à $8 \%$ depuis 1996; il a ensuite décliné jusqu'à la fin des années 2000 pour atteindre sa valeur la plus faible en 2010-2011 (2 \%). La mortalité par la pêche dans les divisions 3LNO a augmenté à partir de la fin des années 1980 pour atteindre un sommet de $29 \%$ en 1997 et se stabiliser à une moyenne de $17 \%$ entre 1998 et 2004. En 2005, cet indice a atteint sa valeur la plus faible (4 \%) et est ensuite demeuré inférieur à $8 \%$. Dans la sousdivision 3Ps, les relevés de recherche canadiens effectués au printemps à l'aide d'un chalut Campelen suggèrent une tendance graduelle à la hausse dans la biomasse de la raie épineuse entre 1996 et 2012; la moyenne étant de 31400 tonnes annuellement. L'indice d'abondance des relevés du printemps dans la sous-division 3Ps a été relativement stable entre 1996 et 2012, fluctuant autour de 23 millions de raies. Après une tendance à la baisse dans les divisions 3LNO entre 1985 et 1995 (relevés de printemps avec le chalut Engel), les indices de la biomasse découlant des relevés de printemps avec le chalut Campelen ont suivi une tendance graduelle à la hausse, avec une moyenne de 85500 tonnes par année. L'indice d'abondance des relevés du printemps dans les divisions 3LNO a été relativement stable entre 1996 et 2012, fluctuant autour de 51 millions de raies. La répartition de la raie épineuse dans la division 3LNOPs a changé depuis les années 1980. Au début, elle était très répandue en concentrations modérées à élevées dans les Grands Bancs, pour ensuite devenir plus restreinte et s'étendre le long de la limite sud-ouest des bancs vers la fin des années 1990 (division 30). La répartition de la raie épineuse entre 2007 et 2012 continue à se concentrer à la limite sud-ouest des bancs de la division 30, dans la sous-division 3Ps et le long du bord du plateau des Grands Bancs dans la division 3LN. Selon les répartitions des longueurs de raies épineuses prélevées dans les relevés de printemps canadiens effectués dans la sousdivision 3Ps et les divisions 3LNO entre 1998 et 2012, le pourcentage le plus élevé de jeunes raies de l'année (longueur totale de 5 à 20 cm ) pour cette période a été observé en 2009. Ce document vise surtout à fournir une mise à jour de l'état du stock de raie épineuse dans la sousdivision 3Ps aux gestionnaires des pêches afin de leur permettre de formuler des mesures de conservation pour ce stock.

## INTRODUCTION

Thorny Skate (Amblyraja radiata Donovan, 1808) is a widely distributed species in temperate and Arctic waters of the North Atlantic. In the western Atlantic, Thorny Skates are distributed from Greenland to South Carolina, and in Newfoundland and Labrador waters (NAFO Div. 2GHJ3KLNOPs), Thorny Skates are found across the continental shelf. Based on the continuous distribution and lack of physical barriers between the south coast of Newfoundland (NAFO Subdivision 3Ps) and the Grand Bank (NAFO Div. 3LNO), Thorny Skate in Div. 3LNOPs is considered to constitute a single stock (Kulka et al. 2004).

Thorny Skates in Div. 3LNOPs have been subjected to commercial fisheries (directed and bycatch) since the beginning of offshore fishing in the late 1940s (Kulka and Mowbray 1999). Commercial catches of skates consist of several skate species; however, Thorny Skate dominates the catch composition. In Canadian commercial catches, about 95\% of the skate catch are Thorny Skates (Kulka and Mowbray 1999; Kulka and Miri 2007); similar to the proportion of Thorny Skate in EU-Spain research survey catches in NAFO Div. 3NO (GonzálezCostas et al. 2012). Therefore, the skate fishery in Div. 3LNOPs can be considered a directed fishery for Thorny Skate.

Thorny Skate are relatively vulnerable to overfishing or environmental perturbations. Life history traits such as slow growth, late sexual maturation, low fecundity, and long reproductive cycles result in low inherent rates of population increase for this species, and lead to low resilience to fishing mortality (Stevens et al. 2000; Dulvy and Reynolds 2002; Frisk 2004; Musick 2004; Sosebee et al. 2008; Patrick et al. 2009).

In assessing the Div. 3LNOPs Thorny Skate stock, the primary abundance and distribution indices used are based on the Department of Fisheries and Oceans Canada (DFO) bottom trawl research surveys conducted annually in spring and fall (commencing in 1971 and 1977, respectively). However, the fall survey does not include Subdiv. 3Ps, which contains a considerable proportion of this Thorny Skate stock.

The primary purpose of this paper is to provide an update of Thorny Skate stock status in Subdiv. 3Ps: especially estimations of stock abundance and distribution, as well as other information on commercial landings and fishing mortality for use by fisheries managers in formulating conservation measures for this stock.

## FISHERY AND MANAGEMENT

## TAC REGULATION

Thorny Skate came under quota regulation in 1995, after a directed skate fishery was established in 1994 by Canada in its Exclusive Economic Zone (EEZ). A Total Allowable Catch (TAC) of 5000 tons for Div. 3LNO and $1000 t$ for Subdivision 3Ps were adopted in 1995; with gear and bycatch policies. In 1996, the TAC was raised to 6000 t for Div. 3LNO and 2000 t for Subdiv. 3Ps. In 1997, the TAC was reduced to 1950 t for Div. 3LNO and 1050 t for Subdiv. 3Ps. Outside Canada's 200-mile limit, catch was unregulated until September 2004, when the Fisheries Commission of the Northwest Atlantic Fisheries Organization (NAFO) set a TAC of 13500 tons for 2005-2009 in Div. 3LNO. This quota was lowered by NAFO to 12000 t for 2010-2011; then to 8500 t for 2012. The TAC for Subdiv. 3Ps was maintained at 1050 t .

## CATCH TRENDS

In NAFO Subdivision 3Ps, NAFO-reported landings (STATLANT-21A) for all countries combined averaged 505 t during 1970-1979, and increased to 975 t in 1980-1989 (Table 1; Fig. 2,5). During the early 1990s, reported landings of skates in NAFO Subdiv. 3Ps declined to 33 t by 1993. In Subdivision 3Ps, total reported landings averaged 1308 t from 1994-2009. Landings during 2010 and 2011 averaged 808 t . It should be noted that the TAC was often exceeded over the past thirteen years.

NAFO data also indicated that Canadian fleets reported the majority of Thorny Skate landings in Subdiv. 3Ps from 1994-2008, while St. Pierre and Miquelon (EU-France) annually reported small skate landings; although none were reported by non-Canadian countries in 2009-2011 (Table 1; Fig. 2,5). Prior to commencement of a new Canadian skate-directed fishery in 1994, skates were routinely discarded at sea. Therefore, reported Canadian landings of Thorny Skate in Subdiv. 3Ps rarely exceeded a hundred tons; with the exception of 1977-1981 when Canadian landings averaged 526 t . Reported Canadian landings averaged 1247 t in 19942007, and 567 t in 2008-2011.

In other portions of the stock area (NAFO Div. 3LNO), Kulka and Mowbray (1998) reported that significant bycatch of skates have been taken since commencement of offshore fishing in the late 1940s; initially by non-Canadian fleets and later by Canadian vessels. Prior to the mid 1980s, non-Canadian fleets comprised the largest component of offshore fisheries on the Grand Bank, and took several thousand tons of skate as bycatch each year. The bycatch derived primarily from the Greenland Halibut fishery (Reinhardtius hippoglossoides) and from the Canadian mixed fishery for Thorny Skate, White Hake (Urophycis tenuis), and Monkfish (Lophius americanus; Kulka and Mowbray 1999). Kulka and Mowbray (1998) estimated that approximately 5000 t on average were discarded annually by Canadian fleets during the 1980s and early 1990s; although only a few hundred tons were recorded in Canada's annual landings statistics during that period. Commercial landings of skates are also never reported by species; except in catch data recorded by Canadian Fisheries Observers at sea.

For Div. 3LNO, NAFO-reported estimates (STATLANT-21A) indicated that landings increased in the mid-to-late 1980s with the commencement of a directed fishery for Thorny Skate (Table 2; Fig. 4,5). In 1985, Spain began targeting skate in a non-regulated fishery in the NRA (Junquera and Paz 1998; del Río and Junquera 2001). In 1985-1991, reported landings averaged 17000 tons, and peaked at approximately 28400 t in 1991. This fishery was mainly prosecuted by Spain, Portugal, USSR, and the Republic of Korea. Non-Canadian landings significantly declined to 5059 tin 1992. In 2000, Russia joined the directed fishery for Thorny Skate. After a peak of 18277 t in 2000, total catches of skate by all countries in Div. 3LNO declined. In 2005-2011, an average of 5548 t of Thorny Skate was reported from Div. 3LNO. Furthermore, it should be noted that an annual average of 13279 t of skate was also landed in 1994-2006 (18 774-ton peak in 2004) by non-Canadian countries, but with no fishing location reported (Table 2). Such NAFO records decreased to a 976-ton average in 2007-2009, and were not available in 2010-2011.

## COMMERCIAL SIZE

Sampling of Canadian commercial catches by at-sea Canadian Fisheries Observers indicated that skates caught in Subdiv. 3Ps by the directed bottom trawl fishery in 1999-2007 were 3497 cm in Total Length (TL), with a mode of 60-67 cm (Fig. 6a; right column). One exception was in 1999, when smaller skates of 18-26 cm TL were also trawled in that fishery, and a dominant mode was seen at 80 cm . Skates trawled in the Subdiv. 3Ps redfish fishery in 20052010 were $36-96 \mathrm{~cm}$ in length, with a mode of $75-79 \mathrm{~cm}$; although smaller skates of $21+\mathrm{cm}$ were also caught in 2005, with a mode of $67-68 \mathrm{~cm}$ (Fig. 6a; left column). The Canadian skate-
directed gillnet fishery in 2000-2002 caught fish of 49-107 cm (TL), with a mode of 76-80 cm (Fig. 6b; left column). In 2008, Canadian longliners directing for skates in Subdiv. 3Ps caught fish of 52-90 cm TL, with a similar mode of 77-79 cm (Fig. 6b; right column).

In 1999-2008, Canadian gillnetters directing for Monkfish in NAFO Div. 30 caught skates of a size range similar to that observed in Subdiv. 3Ps gillnets: 51-110 cm Total Length (TL), with a mode of 72-77 cm (Fig. 6c; Kulka et al. 2006). The skate-directed Div. 30 longline fishery in 2000 caught 56-101 cm fish, with a dominant mode at 80 cm . Thorny Skates caught in various Canadian fisheries in Div. 3LNOPs were not sampled in 2011.

In 2007-2011, commercial length distributions from EU-Portugal, EU-Spain, and Russia in skate-directed trawl fisheries ( 280 mm mesh) of Div. 3LNO in the NRA indicated that the range of sizes caught did not vary between EU-Spain and Russia, and were similar to those reported in previous years (Fig. 6d; Kulka et al. 2006). One exception was the distribution of skates caught by EU-Portugal in Div. 3NO: a $25-66 \mathrm{~cm}$ range with a mode of $38 \mathrm{~cm}(2007,2010)$ and 42 cm TL (2009) was significantly smaller than those of EU-Spain and Russia (27-95 cm; with a mode of 67 cm ). Although these countries used 280 mm mesh in their commercial trawls, this comparison shows that EU-Portugal consistently caught an abbreviated range of smaller skates. Another noteworthy result was reported by EU-Spain in 2008; in which its trawlers also caught a significant mode of 46-49 cm skates (Fig. 6d).
In other directed trawl fisheries (130-135 mm mesh) of Div. 3LNO (NRA) during 2007-2011, length distributions of skate bycatch also did not vary between EU-Spain and Russia (Fig. 6d). However, EU-Portugal caught an abbreviated range of smaller skates in 2007, 2009, and 2010: a 24-72 cm range with a mode of 38 cm (2007), 46 cm (2009), two modes at 54 and 60 cm (2010), and two modes at 60 and 76 cm TL with a maximum length of 84 cm (2011); while EUSpain caught $26-86 \mathrm{~cm}$ skates with a $67-\mathrm{cm}$ mode (2009). In 2008, the size range of skate bycatch reported by EU-Portugal was similar to that of Russian trawlers (28-104 cm with a mode of 58 cm ); although Russia also reported a small catch of 12-18 cm young-of-the-year skates. Russia sampled only 59 specimens during the NAFO Div. 3L Greenland halibut fishery in 2009. Thorny Skates varied between $46-76 \mathrm{~cm}$ in length; with a mode at 61 cm . Although skate bycatch was not sampled by Russia in 2010, a small sample of 34 skates in 2011 indicated a 43-103 cm range with two modes at 49 and 61 cm .

## RESEARCH SURVEY DATA

## CANADIAN SPRING SURVEYS

Stratified-random surveys have been conducted by Canadian research vessels in the spring (April-June) of each year from 1971 to 2012. The survey was initiated in Subdivision 3Ps in 1972. A summary of the stratified-random survey design adopted by the DFO-NL Region can be found in Doubleday (1981). While survey design has remained constant, additional strata have been included in recent years, along with modifications to some of the original strata (Bishop 1994). A significant change in the surveys is the addition of shallower and deeper strata after 1993. Additional causes of variation in spring survey coverage are discussed in detail by Brodie and Stansbury (2007), and Healey and Brodie (2009). The spring survey can be split into three time periods, based on the trawl used in each period: 1971-1982 (Yankee), 1983-1995 (Engel), and 1996-2012 (Campelen; McCallum and Walsh 1996). Conversion factors exist for the Engel to Campelen gear change (Simpson and Kulka 2005); however, data from the Yankee gear series have not been converted.

Canadian spring surveys of Subdivision 3Ps showed that mean catch rates for Thorny Skate in 1996-2012 have been relatively stable at low levels (Fig. 7a). The Subdiv. 3Ps spring abundance index fluctuated around 23 million fish in 1996-2012, and averaged 29 million fish in
the Engel years; except for peaks of 55 million fish in 1985 and 50 million fish in 1991 (Campelen-equivalents; Table 3a; Fig. 8a). Spring relative biomass estimates in the Campelen survey years suggest a gradually increasing trend over that time period; with 21851 tons observed in 1996, and 44310 t in 2011 (Table 3b; Fig. 8a). The spring biomass estimate for 2012 was 33699 t.

In Div. 3LNOPs (combined), spring mean catch rates in 1996-2012 have been stable at low levels, but were considerably higher prior to the mid1990s (Fig. 7b). The spring abundance index fluctuated around 73 million fish for Div. 3LNOPs in 1996-2012, and was considerably higher at 114-214 million fish in 1985-92 (Fig. 8b). Similarly, in 1996-2012, relative biomass estimates of 63 000-165 000 t in Div. 3LNOPs were observed; although 156 000-336 000 t previously occurred in 1985-1991.

Considering Div. 3LNO separately in 1996-2012, spring abundance estimates for Thorny Skate in Div. 3L averaged 9 million fish annually; down from an average of 36 million in the Engel years (Campelen-equivalents; Table 3a). The biomass index in Div. 3L also decreased from an annual average of 42000 tons in 1984-95 to a 12000 -ton average during the Campelen years (Campelen-equivalents; Table 3b). In addition, Div. 3N survey indices declined significantly from Engel to Campelen years: an average annual abundance of 33 million fish decreased to a 15 million-fish average; while an average biomass of 45000 tons dropped to a 27 000-t average. Spring survey indices in Div. 30 reflected much smaller declines between both time series: annual abundance averaged 31 million fish in 1984-95, as compared to a 27 million-fish average during Campelen years; while biomass averaged 59000 tons in Engel years, as compared to a 46 000-ton average in 1996-2012.

## CANADIAN AUTUMN SURVEYS

Stratified-random autumn surveys have been conducted by Canada in NAFO Div. 3L from 1981 to 2011. In 1990-2011, autumn surveys also extended onto the southern Grand Bank in Div. 3NO. Canadian surveys from 1983-1994 were conducted with an Engel trawl, and from 1995-2011 with a Campelen trawl. It must be noted that Canada does not survey Subdiv. 3Ps in autumn, and did not survey Div. 3NO before 1990. Therefore, autumn survey data are not directly comparable to spring indices (which extend over the entire stock area and time period; except for certain Divisions and years). Furthermore, autumn surveys reach deeper maximum depths ( $\sim 1400 \mathrm{~m}$ in recent years) than those in spring ( $\sim 750 \mathrm{~m}$ ). Because the autumn series is not spatially complete over the designated stock area, spring surveys are used as the primary estimator of abundance and biomass trends for this stock. However, autumn indices are still considered in assessments of this stock, because this survey is conducted when a greater proportion of Thorny Skate is available to survey trawl gear (Simpson et al. 2011). During autumn, Thorny Skates are concentrated on the shelf; whereas in spring, part of this population has moved to the shelf edge, and a proportion apparently moves outside of the spring survey area (Kulka et al. 2004). Additional causes of variation in autumn survey coverage are discussed in detail by Brodie and Stansbury (2007), and Healey and Brodie (2009).

Indices of relative abundance and biomass from Canadian autumn surveys in NAFO Div. 3LNO showed that mean catch rates in 1995-2011 had similar trends as observed for the spring time series: autumn indices have fluctuated at low levels (5-10 fish/tow; 7-18 kg/tow) with no general trend; except for a slight increase in catch rates in 2006-2008 (Fig. 7c). Historically, autumn abundance and biomass estimates remained stable at low levels in 1984-89 (i.e., only Div. 3L surveyed), annually averaging 79 million fish and 111000 tons, respectively (i.e., Engel trawl data converted to Campelen-equivalents; Tables 4a,b; Fig. 8c). In 1990-94, abundance and biomass indices averaged 158 million fish (with 1990 peak of 214 million) and 170000 tons (with 1990 peak of 260000 t). In the Campelen survey trawl years of 1995-2011, these indices
annually averaged 77 million fish (with 2008 peak of 105 million) and 113000 t (with 2008 peak of 187000 t ), respectively.

Considering Div. 3LNO separately, abundance and biomass indices for Div. 3L in 1983-88 averaged 84 million fish and 127000 tons, respectively (Campelen-equivalents; Tables 4a,b). In 1990-94, Div. 3L indices averaged 78 million fish and 49000 t ; while Div. 3N and 30 averaged 36 million-44 million fish and 62000 t . In 1995-2011, Div. 3L abundance and biomass indices continued to significantly decline to an annual average of 14 million fish and 17000 t , respectively. Div. 3N indices moderately declined to an annual average of 28 million fish and 46000 t ; while abundance and biomass estimates remained relatively stable in Div. 30 during this period.

## EU-SPAIN SURVEY

Spain initiated a survey in the NAFO Regulatory Area of Div. 3NO in 1995. Initially, the survey was carried out in spring with the C/V Playa de Menduiña using a Pedreira bottom trawl. Since 2001, the R/V Vizconde de Eza replaced the C/V Playa de Menduíña and a Campelen bottom trawl replaced Pedreira gear (González-Troncoso et al. 2012).

Biomass of Thorny Skate was estimated from EU-Spain surveys in the NRA of Div. 3NO in 1997-2011. The survey biomass index showed a consistent increase from 10000 t in 1997 to a peak of 50500 t in 2000 (Fig. 9). However, this index fluctuated annually since 2001; averaging 36000 t in 2001-2006, and 21500 t in 2007-2010; with a significant decline to 10365 t in 2011: the lowest estimate in the time-series since 1998. A comparison of Canadian Campelen spring biomass indices to those of Spanish Div. 3NO surveys in 1997-2011 indicated similar overall trends; even though overall estimates were considerably higher in the former. It must be noted that the Canadian survey covers the entire area of Div. 3NO; whereas the Spanish survey is limited to the NAFO Regulatory Area of Div. 3NO.

## DISTRIBUTION

In Subdiv. 3Ps and Div. 3LNO, the distribution of Thorny Skate has changed significantly since the 1980s. In the early 1980s, skates were widely distributed over the entire Grand Bank in moderate to high concentrations (Fig. 10a-c; Kulka and Miri 2007). By the late 1990s, much of the biomass was concentrated on the southwestern Grand Bank. In 2001-2005, the area of high concentration expanded northward and along the Bank edge. It is important to note that part of this population moves to the shelf edge in spring; thereby moving outside of the Canadian spring survey area (Kulka et al. 2004). However, Thorny Skates are concentrated on the shelf during autumn. In 2006-2012, Thorny Skate distribution continued to be concentrated in Subdiv. 3Ps, on the southwest Grand Bank in Div. 30, as well as along the shelf edge of the bank in Div. 3LN (Fig. 10d,e).

## SURVEY SIZE

Length frequency distribution of Thorny Skate captured in the Canadian Campelen spring surveys of Div. 3LNO and Subdiv. 3Ps from 1997-2012 ranged from 5-105 cm TL (Fig. 11). For most areas and years, a peak of young-of-the-year skates (YOY: 5-20 cm TL) was observed, and averaged 15 cm TL. It should also be noted that the highest percentage of YOY skates for this period was observed in 2009. A dominant peak of larger skates can be seen in spring survey data, with the following modes: 32 cm in 1997; 35 cm in 1998; 40 cm in 1999 and 2000; 44 cm in 2001; 46 cm in 2002; 48 cm in 2003; 55 cm in 2004 and 2005; 62 cm in 2006; 66 cm in 2007, 69 cm in 2008, 71 cm in 2009 and 2010, 72 cm in 2011, and 74 cm in 2012.

## LIFE STAGES

Numbers of male and female Thorny Skate at length caught by Canadian Campelen spring surveys in Div. 3LNOPs during 1996-2012 were partitioned into YOY, immature, and mature (Spawning Stock Biomass: SSB) components (Fig. 12). Various life stages of Thorny Skate underwent different changes in abundance over time. In 1996-2012, Thorny Skate YOY appeared to be relatively stable in abundance; with an average of 5578000 males and 5958000 females. However, abundance estimates of male and female immature skates fluctuated along decreasing trends: from 20540000 males (1998) to 11972000 (2012); from 25289000 females (1999) to 16017000 (2012). Abundance estimates of mature skates fluctuated along an increasing trend: from 9048000 males (1997) to 22169000 (2012); from 4968000 females (1997) to 12922000 (2012).

The ratio of males to females in the sampled population remained relatively constant during 1996-2012; with some fluctuations in these three components (Fig. 13): YOY averaged 0.97 males to females; ratio of immature males to females was always smaller than 0.95 ( 0.73 average); while the mature abundance ratio was always greater than 1.07 (1.49 average). This pattern suggests some difference in the catchability of male and female Thorny Skates at different life stages; potentially due to differential migration into and out of the sampled area (Simpson et al. 2011).

A relationship between mature female abundance and Thorny Skate YOY from Canadian spring surveys of Div. 3LNOPs in 1985-95 (Engel trawl) and 1996-2011 (Campelen trawl) is illustrated in Figure 14. This pre-recruitment index followed an increasing trend in the Engel years; averaging 1.6. However, in the Campelen years, this index declined from 1.9 and 2.4 in 1996 and 1997 (respectively) to an average of 0.9 since 1998; with the lowest value of 0.45 occurring in 2003, and a recent peak of 1.6 in 2009. The latest index (2011) was 1.3. Note that Subdiv. 3Ps was not surveyed in 2006 and one-year-old skates in 2006 were caught only from the shallow ( $<104 \mathrm{~m}$ ) portion of Div. 3NO due to incomplete survey coverage for that year. The pre-recruitment index has been above the Campelen average (1996-2011) for the past three years. However, it is unclear how this index relates to spawning stock recruitment.

## INDEX OF FISHING MORTALITY

A relative Index of Fishing Mortality (Relative F = NAFO STATLANT-21A commercial landings/ Canadian spring survey biomass index) was calculated for Thorny Skate in Subdiv. 3Ps and Div. 3LNO for 1996-2011. Fishing Mortality Index for Subdiv. 3Ps since 1985 was relatively constant; remaining below $5 \%$ (except for $7 \%$ in 2001-2002; Fig. 15). Fishing Mortality in Div. 3LNO increased from the late 1980s to a peak of 29\% in 1997; then stabilized at approximately 17\% during 1998-2004. In 2005, this Index declined to 4\%, and averaged 6\% annually since then.

## SUMMARY

Thorny Skates in NAFO Subdivision 3Ps and adjacent Divisions 3LNO are considered to constitute a single stock. Life history characteristics of Thorny Skate result in low inherent rates of population growth; thereby leading to low resilience to fishing mortality.

Thorny Skate distribution in the entire Div. 3LNOPs Thorny Skate stock area for 2007-2012 continued to be concentrated on the southwest Grand Bank, in Subdiv. 3Ps, and northward along the edge of the Bank in Div. 3LN. Biomass and abundance indices for Div. 3LNOPs underwent a decline during the late 1980s, and remain at relatively low levels. Although the prerecruitment index followed an increasing trend during the Engel years, it declined in the Campelen
years; reaching its lowest value in 2003. This index was above the Campelen average (19962011) over 2009-11. However, it is unclear how this index relates to spawning stock recruitment.

Reported commercial landings of Thorny Skate in Subdiv. 3Ps have declined in recent years. In Subdivision 3Ps, the total reported landings averaged 1308 t from 1994-2009. Landings during 2010 and 2011 averaged 808 t . From a peak of 18277 t in 2000, total reported landings of skate by all countries in Div. 3LNO has declined. In 2005-2009, the average reported landings from Div. 3LNO was 5091 t ; which is approximately a third of the current TAC in Div. 3LNO. Discarding at sea of skate bycatch remains unreported by Canadian and other fishers; resulting in higher removals from the Thorny Skate stock than what available fisheries statistics indicate. As well, commercial skate landings remain unspeciated when reported by Canadian and other fishers to NAFO. Canadian Fisheries Observers do constitute a reliable source of skate commercial catch data by species; including discards at sea, however there is limited coverage in many fisheries.

An index of fishing mortality for Subdiv. 3Ps since 1985 was relatively constant; remaining below $5 \%$. Fishing mortality in Div. 3LNO increased from the late 1980s to a peak of $29 \%$ in 1997; then stabilized at approximately $17 \%$ during 1998-2004. In 2005, the fishing mortality index declined to 4\%, and averaged $6 \%$ annually since then.

The current TAC of 9550 t for skates in Div. 3LNOPs (8 500 t in Div. 3LNO; 1050 t in Subdiv. 3Ps) greatly exceeds average skate landings during a period when rebuilding of this stock has not occurred. It is recommended that annual total catch in Subdivision 3Ps should not exceed 870 tons (i.e., the average reported landings in 2009-2011), and that TAC limits be carefully monitored. Similar reductions in the TAC have occurred in the Division 3LNO portion of this stock.

## ACKNOWLEDGMENTS

We thank Fisheries and Oceans staff who participated in Canadian research surveys, Canadian Fisheries Observers who collected data and specimens aboard commercial vessels under adverse conditions over many years, the Instituto Español de Oceanografía in Vigo (EU-Spain) for data from Spanish research surveys of Div. 3LNO (in the NRA), and l'Institut Francais de Recherche pour l'Exploitation de la Mer (IFREMER) for skate landings data from fisheries conducted by St. Pierre and Miquelon (EU-France) in Subdiv. 3Ps; thereby allowing us to estimate trends and examine various biological aspects of Thorny Skate.

Table 3a. Abundance of Thorny Skate from Canadian spring research vessel surveys in Div. 3LNOPs, 1971-2012. Surveys were conducted with a Yankee bottom trawl (1971-82; data unconverted), an Engel trawl (1983-spring 1995; data converted to Campelen-equivalents), and a Campelen trawl (spring 1996-2012). Spring surveys: NAFO Subdiv. 3Ps was not surveyed in 1971, 2006; NAFO Div. 30 was not surveyed in 1972, 1974, 1983; and NAFO Div. 3N was not surveyed in 1983. Note that deep strata in Div. 3NO were not surveyed in spring 2006.

Table 3b. Biomass of Thorny Skate from Canadian spring research vessel surveys in Div. 3LNOPs, 19712012. Surveys were conducted with a Yankee bottom trawl (1971-82; data unconverted), an Engel trawl (1983spring 1995; data converted to Campelen-equivalents), and a Campelen trawl (spring 1996-2012). Spring surveys: NAFO Subdiv. 3Ps was not surveyed in 1971, 2006; NAFO Div. 30 was not surveyed in 1972, 1974, 1983; and NAFO Div. 3N was not surveyed in 1983. Note that deep strata in Div. 3 NO were not surveyed in spring 2006.

Table 4a. Abundance of Thorny Skate from Canadian autumn research vessel surveys in Div. 3LNO, 19812011. Surveys were conducted with an Engel trawl (1978-94), and a Campelen trawl (1995-2011). Due to vessels' mechanical difficulties, deep strata of Div. 3NO were not surveyed in 2003, 2004, 2006, 2008.

Figure 8b. Canadian spring research survey biomass and abundance indices for Thorny Skate in NAFO Div. 3LNO, and Subdivision 3Ps, 1971-2012. Note that Div. 3LNO were not surveyed in 1983;

Subdiv. 3Ps was not surveyed in 2006; neither the deeper portion (>103 m) of Div. 3NO in that year, due to mechanical difficulties on Canadian research vessels.

Figure 8c. Canadian autumn research survey biomass and abundance indices for Thorny Skate in NAFO Div. 3LNO, 1983-2011. Note that Div. 3L was surveyed in 1981-2011; Div. 3NO were surveyed in 1990-2011. Due to vessels' mechanical diffficulties, deep strata of Div. 3NO were not surveyed in 2003, 2004, 2006, 2008.

Figure 9. Comparison of Thorny Skate biomass indices in 1997-2011 from the Canadian Campelen spring survey in Div. 3NO and the Spanish Campelen spring survey in Div. 3NO. Note that Spanish surveys occur only in the NAFO Regulatory Area (NRA) of Div. 3NO.

Figure 10a. Distribution of Thorny Skate on the Grand Banks (NAFO Div. 3LNOPs), based on Canadian spring surveys in 1980-1991. Green represents low catch rates (kg per tow). Red represents high catch rates. Grey denotes sampled areas with no skate catches. White depicts unsampled areas. Maps taken from Kulka et al. (2004).
 low catch rates (kg per tow). Red represents high catch rates. Grey denotes sampled areas with no skate catches. White depicts unsampled areas. Maps taken from Kulka et al. (2004)

Figure 10c. Distribution of Thorny Skate on the Grand Banks (NAFO Div. 3LNOPs), based on Canadian spring surveys in 2004-2005. Green represents low catch rates (kg per tow). Red represents high catch rates. Grey denotes sampled areas with no skate catches. White depicts unsampled areas.
Maps taken from Kulka et al. (2006).

Figure 10d. Distribution of Thorny Skate on the Grand Banks (NAFO Div. 3LNOPs), based on Canadian spring surveys in 2006 (Upper Left), 2007 (Upper Right), 2008 (Lower Left), and 2009 (Lower Right). Note that Subdiv. 3Ps was not surveyed in 2006; nor was the deeper portion (>103 m) of Div. 3NO sampled in that year, due to mechanical difficulties on Canadian research vessels.

Figure 10e. Distribution of Thorny Skate on the Grand Banks (NAFO Div. 3LNOPs), based on Canadian spring surveys in 2010 (Upper Left), 2011 (Upper Right), and 2012 (Lower Left).

Fig. 11. Length distributions of Thorny Skate from Canadian Campelen spring surveys in NAFO Div. 3LNO and Subdiv. 3Ps, 1997-2011. Vertical bars represent dominant modes of immature skates (excluding YOY): 35 cm in 1998 (Top Panel); 40 cm in 1999-2000; 46 cm in 2002; 55 cm in 2004-2005; 66 cm in 2007, 69 cm in 2008, 71 cm in 2009-2010 (Bottom Panel), 72 cm in 2011, and 74 cm in 2012.

Fig. 12. Estimated abundances of male and female Thorny Skates by life stage in NAFO Div. 3LNOPs from Canadian Campelen spring surveys, 1996-2012. Note that Subdiv. 3Ps was not surveyed in 2006; nor was the deeper portion (>103 m) of Div. 3NO in that year, due to mechanical difficulties on Canadian research vessels.

Figure 13. Ratio of staged male versus female Thorny Skates in NAFO Div. 3LNO and Subdiv. 3Ps from Canadian Campelen spring surveys, 1996-2012. Note that Subdiv. 3Ps was not surveyed in 2006; nor was the deeper portion ( $>103 \mathrm{~m}$ ) of Div. 3NO in that year, due to mechanical difficulties on Canadian research vessels.

Figure 14. Pre-recruits per spawner expressed as number of male and female recruits (in year [y] produced per adult female in year [y-1]) from Canadian Campelen spring surveys in NAFO Div. 3LNO and Subdiv. 3Ps, 1985-95 (Engel; left panel) and 1996-2011 (Campelen; right panel). Note that Subdiv. 3Ps was not surveyed in 2006, and one-year-old skates in 2006 were caught only from the shallow (<104 m) portion of Div. 3NO due to incomplete survey coverage for that year. Both panels are not comparable due to different gear types.

Figure 15. Fishing Mortality Index (catch/spring survey biomass) for Div. 3LNO and Subdiv. 3Ps, 1996-2011. Commercial catch estimates are NAFO STATLANT-21A data; biomass indices are from Canadian spring research surveys. Note that Subdiv. 3Ps was not surveyed in 2006; nor was the deeper portion (>103 m) of Div. 3NO in that year, due to mechanical difficulties on Canadian research vessels
