Foreword

This series documents the scientific basis for the evaluation of aquatic resources and ecosystems in Canada. As such, it addresses the issues of the day in the time frames required and the documents it contains are not intended as definitive statements on the subjects addressed but rather as progress reports on ongoing investigations.

Research documents are produced in the official language in which they are provided to the Secretariat.

TABLE OF CONTENTS

ABSTRACT

The 2015 evaluation of the Northwest Atlantic Fisheries Organization (NAFO) Divisions 4VWX herring considered the data from the 2012-2013 and 2013-2014 quota years. Quota landings of Atlantic Herring (*Clupea harengus*) in 2012-2013 were 46,554 tonne (t) and in 2013-2014 were 50,250t against a Total Allowable Catch of 50,000t for each quota year for the Southwest Nova Scotia/Bay of Fundy (SWNS/BoF) component. Acoustic biomass estimates decreased by 28% in 2013 followed by a 37% increase in 2014 for the SWNS/BoF stock component. In 2014, the SWNS/BoF stock component biomass estimate was slightly above the long term average. It is evident that most of the recent fluctuation in the SWNS/BoF spawning complex is occurring in the Scots Bay area despite an industry imposed catch restriction in the area. In 2013, the fishery catch at age composition by number was comprised of 34% fish at age 2, 21% fish at age 3, 9% at age 4, and 22% at ages 5+. In 2014, the fishery catch at age composition by number was comprised of 30% fish at age 2, 29% at age 3, 12% at age 4, and 21% at ages 5+. In 2013 and 2014, the proportion of the catch age 5+ is the second and third highest proportion of ages 5+ caught since 1994.

Landings from the Offshore Scotian Shelf banks areas continued the downward trend that began in 2012, with landings of only 1,515t in 2013 and 58t in 2014. There were only limited landings of herring from the bottom trawl and mid-water trawl (only 2014) gear in the Offshore Scotian Shelf banks areas for 2013 and 2014. No acoustic survey was completed for the offshore area in 2013 and 2014. Herring abundance in the 2013 and 2014 summer bottom trawl research vessel survey remained relatively consistent with the survey results since 2011. The overall 4VWX area showed an increase in abundance from 2012 to 2013, followed by a subsequent decrease in 2014. This survey has not been considered indicative of overall abundance due to changes in catchability for herring and a lack of year-class tracking.

The recorded landings in the gillnet and trap net fisheries along the coast of Nova Scotia increased from 3,007t in 2012 to 3,937t in 2013 and to 4,760t in 2014. There was a large increase in the surveyed acoustic biomass in the Halifax/Eastern Shore area from an historic low estimate in 2012 of 3,668t, to 6,870t in 2013, and again in 2014 to 9,586t, which is near the five-year average of 10,664t. In the Little Hope area, there was an increase in 2013 to 74,532t from the four-year low in 2012 of 12,756t. The surveyed biomass in the Little Hope/Port Mouton area decreased to 46,077t in 2014, but is still above the five-year average of 37,664t. Only one survey was completed near Glace Bay in 2013 (50t) and none were completed in 2014. In the Glace Bay area, minimal landings of 2t and 1t were reported in 2013 and 2014, respectively. No herring surveys took place in the Bras d'Or Lakes.

Landings in the New Brunswick weir and shut-off fishery were at a historic low of 504t in 2012. Landings increased to 6,431t in 2013 and then decreased to 2,149t in 2014, the second lowest landings for this fishery since 1963. In 2007, landings were 30,944t, the highest in nearly 20 years. The age distribution of fish caught in the New Brunswick weir and shutoff fishery were primarily juveniles, with 93% (2013) and 96% (2014) by numbers at either age 1 or age 2. The success of this passive trap fishery has been historically unpredictable and landings have declined markedly from the 1980s to present. Landings may not be indicative of abundance because catches are extremely susceptible to many factors in addition to abundance, including effort.

Évaluation des stocks de hareng des divisions 4VWX de l'Organisation des pêches de l'Atlantique Nord-Ouest (OPANO) en 2015

RÉSUMÉ

L'évaluation des stocks de hareng des divisions 4VWX de l'Organisation des pêches de l'Atlantique Nord-Ouest (OPANO) en 2015 portait sur les données des années de quota 2012-2013 et 2013-2014. Les quotas de débarquements du hareng de l'Atlantique (*Clupea harengus*) se chiffraient à 46 554 tonnes (t) en 2012-2013 et à 50 250 t en 2013-2014, par rapport à un total autorisé des captures de 50 000 t par année de quota pour la composante du sud-ouest de la Nouvelle-Écosse et de la baie de Fundy. Les estimations de la biomasse de cette composante du stock dans les relevés acoustiques ont diminué de 28 % en 2013, puis ont connu une augmentation de 37 % en 2014. En 2014, l'estimation de la biomasse de la composante du stock du sud-ouest de la Nouvelle-Écosse et de la baie de Fundy était légèrement au-dessus de la moyenne à long terme. Il est évident que la plupart des récentes fluctuations dans ce complexe de stock ont lieu dans la zone de la baie Scots malgré une restriction des prises imposée par l'industrie dans la zone. Voici la composition des prises (par nombre) selon l'âge en 2013 : 34 % de poissons d'âge 2, 21 % de poissons d'âge 3, 9 % de poissons d'âge 4, et 22 % de poissons d'âges 5+. Voici la composition des prises (par nombre) selon l'âge en 2014 : 30 % de poissons d'âge 2, 29 % de poissons d'âge 3, 12 % de poissons d'âge 4, et 21 % de poissons d'âges 5+. En 2013 et en 2014, la proportion des prises de poissons d'âges 5+ représentait la deuxième et la troisième plus grande proportion de poissons de ce groupe d'âge capturés depuis 1994.

Les débarquements des zones des bancs extracôtiers du plateau néo-écossais continuent de suivre la tendance à la baisse qui a commencé en 2012; les débarquements étaient seulement de 1 515 t en 2013 et de 58 t en 2014. Il y a eu peu de débarquements de harengs capturés par chalut de fond et par chalut pélagique (seulement 2 014) dans les zones des bancs extracôtiers du plateau néo-écossais en 2013 et 2014. Aucun relevé acoustique n'a été effectué pour la zone extracôtière en 2013 ou 2014. L'abondance du hareng dans les relevés par navire de recherche au chalut de fond effectués durant les étés 2013 et 2014 est demeurée relativement conforme aux résultats du relevé depuis 2011. Dans l'ensemble, les divisions 4VWX ont connu une augmentation de l'abondance de 2012 à 2013, puis une diminution en 2014. Ce relevé n'a pas été considéré comme un indicateur de l'abondance globale en raison des variations de la capturabilité du hareng et du manque de suivi de la classe d'âge.

Les débarquements enregistrés pour la pêche au filet-trappe et au filet maillant le long de la côte de la Nouvelle-Écosse ont augmenté de 3 007 t en 2012 à 3 937 t en 2013 et à 4 760 t en 2014. Il y a eu une augmentation importante de la biomasse dans les relevés acoustiques menés dans la région de Halifax et de la côte est; elle est passée d'un creux historique de l'estimation de 3 668 t en 2012 à 6 870 t en 2013, puis à 9 586 t en 2014, un chiffre près de la moyenne sur cinq ans (10 664 t). Dans la région de Little Hope, elle est passée du creux historique sur quatre ans de 12 756 t en 2012 à 74 532 t en 2013. La biomasse dans le relevé mené dans la région de Little Hope et de Port Mouton a diminué et est passée à 46 077 t en 2014, mais ce chiffre est toujours au-dessus de la moyenne sur cinq ans de 37 664 t. Un seul relevé a été effectué près de Glace Bay en 2013 (50 t), tandis qu'aucun relevé n'a été effectué dans cette région en 2014. Dans la région de Glace Bay, un faible nombre de débarquements ont été signalés, soit 2 t et 1 t en 2013 et 2014, respectivement. Il n'y a pas eu de relevé sur le hareng dans les lacs Bras d'Or.

Les débarquements provenant de parcs à hareng et de sennes de plage au Nouveau Brunswick ont atteint un niveau historiquement bas de 504 t en 2012. Les débarquements ont augmenté à 6 431 t en 2013; ils ont ensuite diminué à 2 149 t en 2014, le second niveau le plus bas dans cette pêche depuis 1963. En 2007, les débarquements se chiffraient à 30 944 t, soit le niveau le

plus élevé depuis presque 20 ans. D'après la répartition selon l'âge, les poissons pêchés dans des parcs à hareng et des sennes de plage étaient principalement des juvéniles; 93 % (2013) et 96 % (2014), par nombre, étaient d'âge 1 ou 2. Le succès de cette pêche passive au casier est historiquement imprévisible, et les débarquements diminuent de façon marquée depuis les années 1980. Les débarquements ne sont pas nécessairement représentatifs de l'abondance, car les prises sont extrêmement sensibles à de nombreux facteurs en plus de l'abondance, y compris les efforts.

INTRODUCTION

Atlantic Herring (*Clupea harengus*) is a pelagic species found on both sides of the North Atlantic. Herring spawn in discrete locations, to which they are presumed to home. Herring mature and spawn at three to four years of age (23-28cm or 9-11in in length), then begin a predictable annual pattern of spawning, over wintering, and summer feeding, which often involves considerable migration and mixing with members of other spawning groups. Fishing primarily occurs on dense summer feeding, over wintering, and spawning aggregations, and has been dominated by purse seine, weir, and gillnet gear types, with relatively minor landings by shutoff, trap, and mid-water trawl.

The Northwest Atlantic Fisheries Organization (NAFO) 4VWX management unit contains a number of spawning areas, separated to various degrees in space and time. Spawning areas in close proximity, with similar spawning times, and which share a larval distribution area, are considered part of the same component. Some spawning areas are large and offshore, whereas others are small and more localized, sometimes near shore or in small embayments. The situation is complicated further as herring migrate long distances and mix outside of the spawning period, both with members considered part of the same component and with members of other components. For the purposes of evaluation and management, the 4VWX herring fisheries are divided into four components (Figure 1):

1) Southwest Nova Scotia/Bay of Fundy (SWNS/BoF) spawning component (also '4WX' in management plan);
2) Offshore Scotian Shelf banks spawning component;
3) Coastal (South Shore, Eastern Shore and Cape Breton) Nova Scotia spawning component; and
4) Southwest New Brunswick (SWNB) migrant juveniles.

Each component has several spawning areas, and there is mixing of fish among spawning components. Industry and Fisheries and Oceans Canada (DFO) have explored means of managing the complexity within each component (e.g. distributing fishing effort among spawning areas according to their relative size) and accounting for interaction among components (e.g. fishing restrictions on some areas of mixing).

The Georges Bank spawning component is not included in this evaluation except to document Canadian fishing activity. There were no herring landings in 2013 and 2014 from the Canadian portion of Georges Bank, with the last recorded landings observed in 2004. This fishery is included in the Gulf of Maine stock complex and was evaluated in 2009 (DFO 2003a; TRAC 2009) and 2012 (Northeast Fisheries Science Center 2012).

OBJECTIVES AND MANAGEMENT

The 2003 (Evergreen) Scotia-Fundy Herring Integrated Fisheries Management Plan (IFMP) states the principles, conditions, and management measures for the 4VWX herring fisheries (DFO 2003b). The main principle stated in the plan is "the conservation of the herring resource and the preservation of all of its spawning components". The background for the conservation objectives was first developed and reviewed (Sinclair 1997).

Three conservation objectives appear in the plan:

1. To maintain the reproductive capacity of herring in each management unit. Targets include:
    - persistence of all spawning components in the management unit;
    - maintain biomass of each spawning component above a minimum threshold;

- maintain a broad age composition for each spawning component; and
- maintain a long spawning period for each spawning component.

2. To prevent growth overfishing:
    - continue to strive for fishing mortality at or below $F_{0.1.}$
3. To maintain ecosystem integrity/ecological relationships ("ecosystem balance"). Herring is prominent in the diet of many fish, birds and marine mammals and should be managed with these interactions in mind. Specific targets include:
    - maintain spatial and temporal diversity of spawning; and
    - maintain herring biomass at moderate to high levels.

There is evidence that some of these conservation objectives are not being met; however, there has been some improvement from the low level of the spawning stock biomass (SSB[1]) estimates noted in recent assessments (Power et al. 2006, 2007, 2008, 2010a, 2013; Singh et al. 2014a). These objectives require better definition in terms of minimum thresholds and should explicitly list the spawning components in terms of spatial and temporal expectations.

An "in-season" management process, first implemented in the SWNS/BoF fishery during 1995, continues to be used widely within the 4VWX management area (DFO 1997; Stephenson et al. 1996, 1999). The approach encourages surveying using the commercial fleet under scientific direction prior to fishing ("survey, assess, then fish" protocol) to ensure that effort is distributed appropriately among various components of the stock (particularly among spawning components) according to the relative size and current state of each component. The use of this approach in recent years has improved data collection and enabled management decisions to be modified through the involvement of participants and on the basis of up-to-date information.

Collaborative research efforts with the fishing industry have been important in recent years. A major portion of the herring industry (including the purse seine sector and major processors that form the Herring Science Council (HSC) and members of the fixed gear sector) has undertaken a separate Joint Project Agreement with DFO to conduct collaborative scientific projects. The herring industry continues to collect samples and conduct biological sampling, while purse seine and gillnet sectors conducted key acoustic surveys. In 2013 and 2014, field activities were supervised by the HSC manager with assistance from St. Andrews Biological Station (SABS)/DFO staff, individual survey vessel captains, and plant managers. In addition, downloading and data editing services were contracted by the HSC through A. Clay from Femto Electronics Ltd, Lower Sackville, Nova Scotia.

SOUTHWEST NOVA SCOTIA/BAY OF FUNDY SPAWNING COMPONENT

THE FISHERY

In recent years, the herring fisheries in the 4VWX area have been dominated by purse seine, weir, and gillnet, with relatively minor landings by shutoff, and trap. A variety of herring fishing locations, NAFO areas, and fishing ground areas are used to describe fishing activities and group the data for landings and sampling analysis (Figures 2 to 4).

Quota landings for the SWNS/BoF stock component, the only component under a Total

[1] Throughout this document spawning stock biomass (SSB) refers to the spawning stock biomass observed at the time of the acoustic surveys.

Allowable Catch (TAC) control, were 46,554 tonne (t) against a TAC of 50,000t for 2012-2013 quota year. In 2013-2014, landings were 50,250t against a TAC of 50,000t. The quota year begins on October 15th and ends on October 15th of the following year. Landings in the fall 2013 purse seine fisheries for the 2013-2014 quota year were 1,460t. The fall 2014 purse seine fisheries for the 2014-2015 quota year were 1,291t. There was no winter fishery in 2013 or 2014. There were additional landings of 11,778t (2013) and 6,966t (2014) from the non-stock components including Coastal Nova Scotia, the Offshore Scotian Shelf Banks, and SWNB Migrant Juveniles. The landings from New Brunswick weirs and shutoffs fisheries increased from 504t in 2012 to 6,431t in 2013, before decreasing to 2,149t in 2014. Landings from the Coastal Nova Scotia gillnet fisheries also increased from 3,007t in 2012 to 3,937t in 2013 and again in 2014 to 4,760t. The landings from the Offshore Scotian Shelf Banks component increased from 1,255t in 2012 to 1,515t in 2013, before decreasing to a historical low of 58t in 2014 (Tables 1A, 1B, 2A, 2B and 3).

Landings for SWNS/BoF stock component have recently tracked the TAC, with most of the quota (and on occasion slightly above) being taken each year since 2002 (Figure 5). In the 2012-2013 quota year, landings were 3,446t below the TAC. In 2013-2014 landings were 250t above the TAC. As a result of the reduced quota since 2005, total landings from this component have remained low (Table 3). Tables 4A and 4B provide the purse seine landings (in tonnes and in percentages) by fishing grounds from 1985-2014 for the 4WX stock component. Throughout the history of this fishery most landings have been caught by purse seine gear, with the 4X summer purse seine fishery being the largest (Table 3; Figures 6, 7A and 7B). Landings by the purse seine sector accounted for 97% and 95% of the component landings in 2013 and 2014, respectively, with minimal landings by the gillnet sector (higher than in recent years; 1,270t in 2013 and 2,102t in 2014) and continuing a below average trend in landings from the Nova Scotia weirs (43t in 2013 and 166t in 2014; Tables 1A and 1B, respectively). According to the IFMP, 80% of the TAC is initially allocated to the mobile gear sector and 20% to the fixed gear sector and, as in past years, a transfer of unused quota to the mobile fleet occurred near the end of the fishing season.

Purse seine landings are summarized by fishing grounds using definitions of the various grounds based on groupings of 10-minute boxes of latitude and longitude (Tables 4A, and 4B; Figure 4). The largest proportions of landings came from fishing grounds in the German Bank (29% in 2013, 30% in 2014), Grand Manan (27% in 2013; 20% in 2014) and Gannet Dry Ledge (13% in 2013; 26% in 2014) areas (Table 4B; Figure 8). The purse seine landings from fishing grounds in the Gannet Dry Ledge area in 2014 were their highest proportion to date, although not by landing tonnage (12,659t in 2014 compared to 18,527t in 1992, Tables 4A and 4B). Scots Bay landings decreased from 11% in 2012 to 10% in 2013 and 9% in 2014. Landings from Scots Bay have decreased each year since 2011 (5,130t) to 2014 (4,498t). Landings from the New Brunswick coastal area increased from the 17-year low in 2012 of 132t to 1,760t in 2013 before decreasing again in 2014 to 557t. Landings were again below the long term average from the Long Island and Trinity Ledge areas. Landings from the Long Island area increased significantly from 2012 (160t) to 4,942t in 2013, but decreased in 2014 to 2,607t. In comparison, landings from the Lurcher area continue to be above the long-term average of 1,581t in both 2013 (2,872t) and 2014 (2,134t).

Purse seine landings of 1,460t were reported in the October/November 2013 fall fishery and 1,291t were reported in the October/November 2014 fall fishery (Tables 2A and 2B; Figures 9A and 9B). There was no winter fishery reported in 2013 or 2014 (Tables 1A and 1B). Fisheries that occur at the beginning of each quota year are usually concentrated on the New Brunswick side of the Bay of Fundy.

The largest single fishery of the SWNS/BoF stock component is the summer purse seine fishery, which occurs from May to October in the Bay of Fundy area. In 2013, this fishery

occurred in similar areas and months as in previous years with total landings of 44,884t (Table 1A; Figure 10A). The 2014 fishery took place in similar areas and months with total landings of 46,522t (Table 1B; Figure 10B). A large portion of this fishery is directed toward pre-spawning, feeding aggregations in May and June. Landings on the major spawning grounds during the spawning period in Scots Bay and on German Bank are found primarily within the pre-defined acoustic survey areas (Melvin and Power 1999).

As in recent years, there was no winter fishery in Chedabucto Bay and the majority of the fall herring landings came from the New Brunswick side of the Bay of Fundy (Table 4A; Figures 9A and 9B).

Landings of non-stock component herring by purse seine, which occurred solely from the Offshore banks area on the Scotian Shelf in 2013 and 2014, increased from 1,210t in 2012 to 1,466t in 2013 (Table 5; see: Figures 38A and 38B). In 2014, landings of non-stock component herring by purse seine were at a 25-year low of 23t. There have been no landings from the Georges Bank, Liverpool, Shelburne and Halifax areas since 2006. In 2013 and 2014, there were also no landings from the Western Hole area (Table 5).

Main Fishing Areas for the SWNS/BoF Component

The main fishing areas for the SWNS/BoF component are the German Bank, Scots Bay, and Trinity Ledge areas, which also include spawning grounds fisheries. Additional amounts of fishing occur in the Gannet Dry Ledge, Grand Manan and Long Island Shore stock areas. Recently, only limited fishing has been occurring by the Nova Scotia weirs in St. Mary's Bay, although some weir landings are now being reported in the upper Bay of Fundy near Parrsboro. In the past, there was also an occasional small gillnet fishery in the spring on spawning herring near Spectacle Buoy, which is just southeast of Yarmouth, Nova Scotia; however, there has been no reported landings from this area since 2011. Last, there has been a new trend of increasing gillnet landings in Scots Bay and German Bank, areas previously not fished by the gillnet fleet (Table 6).

German Bank

German Bank is one of the primary herring fishing grounds in the Bay of Fundy area. In recent years, there has been a trend of increasing gillnet landings from German Bank (Table 6). Since 1985, landings from this area have ranged from 9,003-35,977t during the main fishery period from early-May to late-October (Table 7). Purse seine landings during the pre-spawning period (defined as the period from January 1st to August 14th) increased from 5,369t in 2012 to 6,324t in 2013 and 15,077t in 2014. The 2014 pre-spawning period landings are near to the highest landings since 1985, which were 18,508t in 1999 and 16,845 in 2008 (Table 7). Purse seine and gillnet landings during the spawning period (defined as the period from August 15th to October 15th) decreased from 29,582t in 2012 to 12,700t in 2013 and to 10,080t in 2014. The contribution of German Bank landings to the overall TAC decreased from 70% in 2012 to 38% in 2013 before increasing again up to 50% in 2014 (Table 7; Figure 11).

The distribution of catches (purse seines only) on German Bank in the 2013 and 2014 pre-spawning period (January 1st to August 14th) are presented in Figure 12. Within the spawning box area, catches on German Bank during the spawning period are primarily of spawning "roe" fish (Figure 13). However, immature juvenile herring were collected in the spawning box area by the Canadian Coast Guard Ship (CCGS) *Alfred Needler* between July 29th and August 14th in 2013. Similarly, in 2014, there was a high percentage of Stage 1-2 "immature" fish and herring of less than 23cm in length collected by the CCGS *Alfred Needler* between May 14th and August 4th. In 2013 and 2014, catches of spawning herring were generally spread within the 'strata box' (which is used as the primary search area in acoustic surveys), with localized groups seen in both the northern and southern portions (Figure 13). In 2013, the catches of spawning herring

extended farther south than in the previous year, extending outside of the standard survey area. In comparison, in 2014 the catch was again predominantly localized within the 'strata box', with less of a north-south division in the catches. As in 2012, the fishery catches during the spawning period in 2013 occurred throughout August to October, with the majority occurring between mid-August and mid-October. In 2014, however, the catches shifted significantly earlier, occurring predominantly in August and tapering off in September (Figure 14). The total landings for the German Bank area decreased to 19,025t in 2013, from the near high of 34,951t in 2012, before increasing in 2014 to 25,157t in 2014 (Table 7). The timing and amount of the landings on German Bank may also be influenced by industry measures to limit catches to less than 50% of the TAC on the German Bank fishing ground.

Scots Bay

The Scots Bay herring purse seine fishery has been an important component of the summer fishery. Since 1987, landings have ranged from 902t in 2009 to 24,388t in 2004 during the period of late-June to late-August/early-September (Table 8; Figure 15). The earliest catch dates for the Scots Bay herring purse seine fishery occurred in 2013 and 2014 (Table 8). Since 2006, the Scots Bay fishery has been restricted by a 5000t cap self-imposed by the herring industry due to the poor performance of the spawning component. The highest recorded landings of 24,388t, and the most days with catch recorded, occurred in 2004 (Table 8). Landings in 2013 and 2014 continued the decreasing trend since 2011 (5093t). In 2013, the Scots Bay herring purse seine landings were 4,702t (over a 71-day fishing period) and 4,498t (over a 71-day fishing period in 2014) (Table 8; Figure 16). Most of the catches in 2013 and 2014 were located within the defined survey box area. Substantial catches also occurred outside the box either in Advocate Bay or into the upper part of Scots Bay, predominantly in 2013 (Figure 16). The catches were spread throughout the season in both 2013 and 2014 (Figure 17).

Trinity Ledge

In this report, the stock gillnet landings were re-analyzed such that now Table 9 presents the landed weight within the Trinity Ledge survey area and the exploitation percentage of the acoustic surveyed biomass. Landings within the Trinity Ledge survey area decreased from 177t in 2012 to 99t in 2013 (between August 13th to September 18th) and increased to 123t in 2014 (between August 12th and September 30th) (Table 9; Figures 18A, 18B and 19). In 2013, the total estimated biomass (with the Calibration Integration Factor, or CIF) from the acoustic surveys followed a similar pattern, decreasing to 950t in 2013 from 2,754t in 2012 and increasing to 4,772t in 2014 (Table 9; Figure 19). The exploitation rate was at its highest percentage since 2007 in 2013 (10%; Table 9). Additional work is required to monitor the status of this spawning area, which once supported a major portion of the overall stock landings (Tables 4A and 4B; Figure 8).

Nova Scotia Weirs

Landings from Nova Scotia weirs (4Xr) located in the Bay of Fundy near Parrsboro, Nova Scotia, remained quite low at only 43t in 2013 and 166t in 2014 (Tables 3 and 10; Figure 20). There has also been a decline in the total number of herring weirs to 14 active weirs in the last decade, down from 20 or more in the 1980s, with only three reporting catches in 2013 and 2014 (Table 11). In 2011-2012, the seasonal timing of the Nova Scotia weir landings was noted to have shifted to the later months of the season, with most of the catch in July, August, and September (Table 10). However, in 2013 and 2014, the catches were earlier in the year. There were no herring weir landings in August or September in either 2013 or 2014 and, in 2014, all herring weir landings occurred in May and June. Landings for the Nova Scotia weirs have been highly-variable in recent years and are not consistent in amount or timing, with catches occurring early in the season in the 1990s and then later in the season over the last decade.

Spectacle Buoy

In the past, the spring gillnet fishery for roe has occurred for a short period in June in the vicinity of Spectacle Buoy located southeast of Yarmouth, Nova Scotia. The fishery is dependent on fish availability and to some extent market conditions, and may or may not occur in any given year. In 2008, only one landing of 6t was reported and very limited acoustic surveys were completed. In 2009, there was little fishing (less than 1t) and no survey activity in this area, while in 2010 there was no fishing and a survey biomass of 1,859t based on two properly conducted surveys. In 2011, only 1t catch was reported with an estimated survey biomass of 282t from one properly conducted survey. There was no fishery or surveys conducted in 2012 to 2014 (Table 9).

RESOURCE STATUS

Commercial Catch Rate Indices

Catch and effort for gillnet data in the SWNS/BoF spawning component have been examined in previous assessments. The data indicated little trend and were considered unrepresentative due to the small amounts and variable timing and location of catch and effort (Power et al. 2004) (Table 3). The 2013 landings from the gillnet fishery in the SWNS/BoF spawning component increased from 471t in 2012 to 1,270t in 2013 and again to 2,102t in 2014 (Table 3).

Purse seine landings comprise the majority of the overall landings and are allocated 80% of the TAC for the SWNS/BoF component under the current IFMP. The purse seine landings have fluctuated between 44,476t and 103,537t since 1989, primarily reflecting changes in the TAC (Table 12; Figure 21). The number of boats fishing and days fished has dropped since 1990 due to fleet rationalization. This has resulted in increases in landings per boat and catch per day in recent years, but the landings are also affected by the reduced TAC. In general, purse seine catch rates are not considered to reflect trends in population abundance due to the nature of herring schooling behavior and the acoustic technology used to find these concentrated schools. Catch rates can remain high or stable even at low stock levels. These data are reported to document the overall effort by the purse seine fleet (Table 12).

Acoustic Surveys

Automated acoustic recording systems deployed on commercial fishing vessels have been used since 1997 to document the distribution and abundance of herring. Scheduled surveys are now conducted annually with surveys completed every two weeks on each of the main spawning components. An index of SSB is estimated by summing these results (Melvin and Power 1999). Throughout this document SSB refers to the spawning stock biomass observed at the time of the acoustic surveys.

The 2008 biomass estimate in the traditional survey areas of Scots Bay, Trinity Ledge and German Bank (264,900t) was the lowest recorded since acoustic surveys began in 1997. Since 1999, the total SSB has fluctuated between 264,900t and 576,700t. The estimates in 2011 and 2012 tended upwards (448,8001t in 2011 and 476,000t in 2012) being at or above the long term average. This represents an increase of 44% from 2010 to 2011 and an increase of 16% from 2011 to 2012. In the last two years, a substantial decrease in the overall SWNS/BoF stock biomass estimate was observed in 2013 (341,694t, 95% confidence interval (C.I.): +/-160,115t), with the estimate returning to slightly above the long term average in 2014 (468,736t, 95% C.I.: +/-185,679t). It is evident that most of the recent fluctuation in the SWNS/BoF spawning biomass is occurring in the Scots Bay area, although industry has imposed a catch restriction of 5,000t in Scots Bay since 2006. Caution should also be observed in the German Bank area as a result of a trending decline over the previous four years in the estimated biomass for this area (Table 13; Figures 22 and 23).

Spawning Ground Turnover Rates from Tagging Studies

The current acoustic survey methodology on spawning grounds is dependent on the periodic turnover of spawning fish. Acoustic surveys are required to be separated by 10 to 14 days to allow for fish turnover and to prevent double counting (Power et al. 2002). Melvin et al. (2014) updated the tagging study on German Bank during the spawning period that was completed in 2011. Approximately 23,000 spawning herring were marked and released on German Bank during the 2009-2011 spawning season. This data was combined with data from previous Scots Bay and German Bank tagging studies for analysis. Overall, 13% of tagged fish in Scots Bay and 19% on German Bank were recaptured after two weeks. Regression analysis indicates a strong relationship between the days at large and the proportion of fish remaining on the bank. Corrections for the 2012 Scots Bay and German Bank spawning biomass for elapsed time reduced the biomass from 397,590t to 308,069t, or by 22.5%. A review of this study and its results should be conducted at the next framework review of 4VWX herring, as well as, if and how this data should be incorporated into the assessment. Incorporation will require that adjustments also be made to the reference points that utilize acoustic biomass estimates.

Exploitation Rates on Spawning Grounds

The acoustic survey estimates and landings from individual spawning areas were examined to estimate relative exploitation rates on different spawning groups and the overall SWNS/BoF component. Exploitation was calculated as the ratio of landings divided by acoustic survey biomass. These estimates can be used to assess the impact of fishing and also to estimate the relative size of individual spawning units within the SWNS/BoF component. These rates are dependent on the assumptions that the acoustic survey SSB is complete, that catches have been properly allocated and, most critically, that the acoustic SSB provides an absolute measure of biomass. As a result of these uncertainties, the absolute fishing mortalities cannot be determined or inferred, but instead the trends over time may be used in a relative sense from year-to-year.

For this analysis, as in previous years (Singh et al. 2014b), the three main spawning areas of Scots Bay, German Bank, and Trinity Ledge, which have received relatively consistent survey effort since 1999, were used (Table 14-A1). The acoustic SSB for nearby Seal Island and Spectacle Buoy areas were allocated to the German Bank spawning area. All catches captured on each spawning ground throughout the year were assumed to be site specific (Table 14-C1), while landings from other non-spawning areas were allocated based on the relative spawning ground SSB proportions from annual acoustic surveys (Table 14-A2). The adjusted total landings were thus made equal to the reported stock landings (Table 14-C2). Exploitation rates were then calculated (Landings/SSB) for both the actual landings from the spawning grounds and the overall adjusted landings as proportions (Table 14-E1, E2).

The trends in spawning area proportions estimated from acoustic surveys (Table 14-A2) were stable between 2005 and 2010, with approximately 80-90% of surveyed SSB found in the German Bank area and 10-20% in the Scots Bay area; however, those proportions have changed dramatically since 2011. On German Bank, the proportions are below average and varied between 50% (2014) and 77% (2013), while in Scots Bay the proportions were above average and varied between 22% (2013) and 49% (2014) (Table 14-A2).

Since 1999, calculation of exploitation rates by areas (Table 14-E2) indicated that larger areas (Scots Bay and German Bank) have an average exploitation rate of 18% and 15%, respectively, while the smaller area (Trinity Ledge) had an average exploitation rate of 55%. The combined overall adjusted exploitation rate for these three areas ranged from 10-25% from 1999 to 2014 (Figure 24). These exploitation rates are useful for year-to-year comparisons and indicate that the overall adjusted estimate was stable from 14-18% between 1999 and 2004. There was an increase in the overall adjusted exploitation rate to 21% in 2005, coinciding with a large

decrease in total survey biomass. The rate declined to 13% in 2007 followed by an increase to the series high of 25% in 2008. From 2009 to 2012, the rate declined from 14% to 10%, increasing up to 18% in 2010. In 2013, the overall adjusted exploitation rate increased again to 14% and decreased in 2014 to 11% (Table 14-E2; Figure 24).

Biological Sampling

Comprehensive biological sampling continued for this fishery with substantial involvement of the fishing industry, which provided length frequencies, maturity reports, and frozen fish samples for analysis by DFO personnel. In 2013, a total of 1,947 samples (329,054 fish) were measured for length, while 4,455 fish were sampled for sex, weight, maturity and age (Table 15A). In 2014, a total of 1,748 samples (287,492 fish) were measured for length, while 5,761 fish were sampled for sex, weight, maturity, and age (Table 15B). The sources of the samples are provided in Table 16, with the majority supplied by the processing industry since 1996. Additional samples were collected by DFO personnel, observers deployed on fishing vessels, and DFO research surveys. Sampling from the commercial fishery coincided with the spatial and temporal distribution of the fishery, and additional sampling from research vessel surveys during the spring and summer resulted in widespread geographic coverage as in the past (Figures 25A and 25B).

Catch at Age

Consistent with previous assessments, the catch at length and age were constructed using the 'Catch at Age' application (version 11.5), a program that computes catch at age statistics as part of the stock assessment process. Data files used by 'Catch at Age' were selected directly from biological sample data in the Pelagic Samples Database, Maritimes Region, DFO. These data included a 2% adjustment for the shrinkage due to freezing on the length measurements for frozen samples (Hunt et al. 1986).

The size and age composition was characterized by month, unit area, and gear type using all available length and age samples in 2013 (Table 17A) and 2014 (Table 17B). The required length-weight relationships were calculated on a monthly basis. The catch at age statistics were calculated from length frequency and age-length samples expanded to total landings using appropriate monthly length-weight relationships. The data were grouped and age-length keys were applied to length frequencies to produce catch at age statistics by NAFO unit area, gear-type and month.

Tables 18A and 18B and Figures 26A and 26B present monthly and seasonal catch at age data for the 2013 and 2014 summer purse seine fishery conducted on the SWNS/BoF spawning component (4WX stock). The monthly purse seine catch at age (Tables 18A and 18B, Figures 26A and 26B) during 2013 and 2014 indicate that catches later in the season tend to consist of larger percentages of younger fish (ages 2 and 3). This is a concern since younger fish would not yet have contributed to spawning. Tables 19A and 19B and Figures 27A and 27B present catch at age by fishing ground for the 2013 and 2014 summer purse seine fishery conducted on the SWNS/BoF spawning component (4WX stock). Table 20A presents the catch at age data for the 2011-2012 for the purse seine, gillnet, and weir fisheries conducted on the SWNS/BoF spawning component (4WX stock). Tables 20B and 20D and Figures 28A and 28B present the catch at age data for the 2012-2013 and 2013-2014 quota years for the purse seine, gillnet, and weir fisheries conducted on the SWNS/BoF spawning component (4WX stock). Tables 20C and 20E present the comparisons of herring catch at age for 2011-2012 versus 2012-2013 quota years (Table 20C) and 2012-2013 versus 2013-2014 quota years (Table 20E).

The 2013 catch was dominated by the 2012 year-class (at age 2), representing approximately 34% by number. The 2011 year-class (at age 3) was the second most important by number at 21%. The 2013 catch by weight of the herring landed was spread equally (17- 21%) across four year-classes: at age 2 (2012), age 3 (2011), age 5 (2009), and age 6 (2008) (Table 21B;Figure

29A). The proportion of the catch older than age 5 increased in 2013 to 21% (by numbers) from 14% in 2012 (Tables 20A and 20B). The total number of fish of all ages removed by the fishery in 2013 was calculated to be 429 million, a decrease of 3.5 million (or 1%) from 2012.

In the 2014 landings, the 2013 and 2012 year-class (at age 2 and 3, respectively) represented approximately 30% and 29%, respectively, of the numbers of herring landed in the SWNS/BoF component (Tables 20D and 21B; Figure 29B). These large percentages of age 2 and 3 herring in the landings is a concern since they would not have had a chance to contribute to spawning. Industry has implemented measures to monitor catch size distribution and to limit the amount of small fish landed. By weight, the 2012 year-class (at age 3) represented 25% of the herring landed in the SWNS/BoF component. The second most important age class by weight was the 2009 year-class (age 6). The proportion of the catch older than age 5 increased in 2014 to 22% (by numbers) from 21% in 2013. The total number of fish of all ages removed by the fishery in 2014 was calculated to be 448 million, an increase of 19.7 million or 5% from 2013.

The number of age 2 fish decreased from 34% in 2013 to 30% in 2014 (Figures 29A and 29B). Most of this decrease is a result of decreased catches in the Grand Manan and Long Island Shores areas, which are dominated by age 2 fish. The number of age 3 fish increased from 21% in 2013 to 29% in 2014. Most of that increase is a result of increases in catches on Grand Manan Banks and Gannet Dry Ledges areas, where the percentage of age 3 fish is similar between years. Despite an overall decrease in age 2 fish caught in 2014 compared to 2013, most of the stock fishing grounds showed increases in the proportion of age 2 fish caught.

The historical time series of catch at age data indicates there have been few fish older than age 8 since 1995 and this time series continues to be dominated by ages 2-5 (Tables 21A and 21B; Figure 30). Older ages had been a feature when strong year-classes (i.e. 1976 and 1983) were progressing through the fishery. These stronger year-classes had persisted in the catch to older ages in the 1970s through to early-1990s. In recent years, the rapid decline of year-classes in the landings and the continued lack of older fish imply a high total mortality (Power et al. 2006). The trend toward catches at younger ages results in reduced yield and is reflected in the increase in the number of individual fish caught as the landings have decreased (Figure 31). In 2013 and 2014, the proportion of the catch at age 5+ was 21% and 22% (by numbers), respectively, representing the second and third highest proportion of age 5+ fish caught since 1994 (25% in 2007).

Weight at Age

The average (fishery weighted) weight at age continues to be below the long term 1965-2014 average, possibly reflecting changes in fishing patterns and timing (Table 22; Figure 32). There was a general decline in weight at age that occurred for all ages around 1987 (Figure 33). A further decline is also apparent for older ages (6 to 10) after 1997, with ages 8+ fish now consistently below 300g. Consistent with the data for 2012 in the previous assessment (Singh et al. 2014a), the 2013 and 2014 weights at age in particular are similar to the most recent five-year and ten-year averages, which are consistently less than the overall time series average (Figure 32).

Total Mortality Estimates from Acoustic Data

Estimates of total mortality (Z = Fishing mortality (F) + Natural mortality (M)) were calculated using the acoustic catch at age data. When completed in this manner, Z calculations are typically quite variable, but can often be used to detect broad patterns. Total mortality was calculated using ages 4 to 8 combined compared with ages 5 to 9 in the following year (overall SWNS/BoF component: Table 23A; Figure 34A, German Bank: Table 23B; Figure 34B and Scots Bay: Table 23C; Figure 34C). The acoustic age composition from 1999 to 2014, and the biological characteristics from sampling from 1999 to 2014, are shown in Table 24 for the overall SWNS/BoF component (A), German Bank (B), and Scots Bay (C). The results for 2000 to 2014

have highly variable Z values, ranging from: -0.3 to 1.3 for the overall SWNS/BoF component (Figure 35A) and German Bank spawning area (Figure 35B), and from -1.2 to 2.2 for the Scots Bay spawning area (Figure 35C). There is no apparent trend, as the series are very short. However, for the overall SWNS/BoF component, the trend appears to be increasing estimates of total mortality in the past two years after an overall decreasing trend in the four years prior to that. Similarly, for the German Bank spawning area the trend appears to be decreasing estimates of total mortality from 2008-2012, a leveling off in 2013, and an increase in 2014. For Scots Bay, the estimates of total mortality have had an overall decreasing trend from 2005-2012, with an increase observed in the past two years.

Stock Trends

The 2008 acoustic biomass estimates decreased 42% for all survey areas in Scots Bay, Trinity Ledge, and German Bank, and were the lowest recorded estimates since acoustic surveys began in 1997 (Power et al. 2010a). There was an increase in 2009 to 486,900t and a decrease in 2010 to 312,100t. The acoustic SSB estimate for the overall SWNS/BoF component increased in both 2011 and 2012 to 448,771t and 476,026t, respectively. In 2013, the acoustic SSB estimate for the overall SWNS/BoF component decreased by 28% to 341,694t (95% C.I.: +/- 160,115t) before increasing to 468,736t (95% C.I.: +/- 185,679t) in 2014. Overall, the SSB estimate in 2014 was above the long-term average of 450,010t (Table 13).

In the past, industry and DFO have explored ways to manage the complexity within each component (e.g. distributing fishing effort among spawning areas according to their relative size) and accounting for the interaction among components (e.g. fishing restrictions on some areas of mixing). The total number of fish removals decreased in 2013 by 1% from 2012 and increased in 2014 by 5%. The largest yearclass in the 2013 and 2014 catch were the 2 (2013: 34%; 2014: 30%) and 3-year olds (2013: 21%; 2014: 29%), the 2012 catch was primarily comprised of 4-year old (27%) and 2-year old (25%) fish. The large number of 2-year old fish in the 2013 catch came mostly from the Grand Manan and Long Island Shore areas (Table 19A). In 2014, the large number of 2-year old fish in the landings came from four areas: Grand Manan Banks, Long Island Shore, Gannet Dry Ledge and Trinity Ledge. However, neither 2013 nor 2014 provide an indication of a strong year-class (Figure 30).

Conservation Limit Reference Point

In 2012, a conservation limit reference point (LRP) for the SWNS/BoF herring spawning component (German Bank and Scots Bay) was identified as the 2005-2010 average acoustic survey biomass (377,272t), below which the risk of serious harm is unacceptable (Clark et al. 2012). Figure 36A presents the acoustic spawning biomass for the period 1999 to 2014 along with the three-year moving average, the long-term average, and the LRP. Figure 36B presents the same data as a relative biomass index. The 2010 biomass estimate was below the LRP by 17%. The biomass estimates increased above the LRP by 19% in 2011 and by 28% in 2012. The biomass estimate was again below the LRP by 8% in 2013 and returned above the LRP in 2014 by 24%.The three-year moving average increased above the LRP in 2011 and changed very little in 2012. Since 2012, the three-year moving average has been increasing slightly each year.

SOURCES OF UNCERTAINTY

When using acoustic survey results as a measure of absolute abundance there are numerous variables for which information is lacking (e.g. residence time on the spawning grounds and estimation of biomass in the acoustic dead/blind zones at the surface and close to bottom). Between 1999 and 2003, acoustic survey results were used as minimum estimates of absolute SSB abundance and the population was considered to be approximately 500,000t. An SSB of that size would have been expected to result in substantial growth of the population, improved

age composition and low fishing mortality, given reasonable recruitment and the landings over that period. This has not occurred.

The assumption that surveys are additive continues to be a source of uncertainty (DFO 2007). Other significant issues relate to the completeness of coverage of the survey area on Trinity Ledge, inter-annual turn-over processes on each area, and factors that influence the target strength and acoustic backscatter (DFO 2007). A review of the tagging study by Melvin et al. (2014) on German Bank could help reduce uncertainty about residence time. Additionally, the mechanisms causing changes in fish weight-at-age are not understood.

The acoustic survey index provides fisheries independent information on the SSB but does not provide data on younger age classes. The size of recruiting herring year-classes is highly variable and with no index of recruitment, a large fraction of the catch is dependent on recruiting year-classes of uncertain abundances. Advice on stock status uses relative trends in SSB and exploitation rate because there is no accepted analytical assessment model. This creates a difficulty in putting current SSB in a historical context as acoustic data only exist for 1999-2014.

ECOSYSTEM CONSIDERATIONS

Herring is a keystone forage species prominent in the diet of many fish, seabirds, and marine mammals, and should be managed with these interactions in mind. At present, use of a natural mortality rate of 0.2, and maintenance of SSB at moderate to high levels, are assumed to take these interactions into consideration.

Management initiatives to protect spawning components are intended to maintain the spatial and temporal diversity of herring spawning. Any increase in the fishing on juveniles, which are of mixed or unknown stock affinity, would be inconsistent with this objective.

MANAGEMENT CONSIDERATIONS

The in-season management approach, which spreads effort in the fishery spatially and temporally among spawning components, is seen as beneficial in achieving conservation objectives. The “survey, assess, then fish” protocol is effective in spreading the catch appropriately among spawning components in proportion to their relative size and is considered an important safeguard. Acoustic surveys have become critical to stock status evaluation. It is important that there be continued attention to coverage and survey design in order to assure year-to-year consistency in all spawning areas.

Evaluations of progress against the conservation objectives in the IFMP from 2006 to 2009 are documented in Power et al. (2010b). In the 2012 fishery evaluation, the assessment of SSB showed that the 2011 and 2012 SSB estimates increased by 44% and 6% over the previous year’s estimates in the main areas for Scots Bay and German Bank (Singh et al. 2014b). In 2013, SSB estimates decreased by 28% over the 2012 estimates, before increasing by 36% over the previous year’s estimate in 2014, which was 2% lower than the 2012 estimate. The amount of spawning fish documented on Trinity Ledge in 2013 and 2014 was extremely low (950t and 4,772t, respectively). This assessment indicates that most of the recent fluctuation in the SWNS/BoF spawning complex SSB is occurring in the Scots Bay area although industry imposed a catch restriction of 5000t in Scots Bay since 2006. In 2013, there was a substantial decline, with a biomass estimate of less than half of the previous year to 76,218t (95% C.I.: +/- 20,984t). The surveyed biomass, however, increased in 2014 to a new high of 230,930t (95% C.I.: +/- 106,514t). There has been less variability in the SSB estimates on German Bank in the last five years; however, during this time the estimate has decreased at an average annual rate of 8%.

The SSB for the last three years remain below the long term average. Scots Bay showed a slight increase in the length of spawning period in comparison to recent years (as a result of an

earlier start date), while German Bank showed a slight decrease in the length of spawning period in comparison to recent years (as a result of an earlier end date). Virtually no spawning occurred on Trinity Ledge; it is therefore difficult to determine the duration of the spawning period and the recorded spawning area is quite small. There was a change in spatial distribution in Scots Bay in comparison to the four previous years, particularly in 2014, with more catches and biomass inside the survey area box and wider spread throughout the box. On German Bank, the spawning distribution in 2013 and 2014 was generally spread within the 'strata box', with localized groups seen in both the northern and southern portions. In 2013, the catches of spawning herring extended farther south than in previous years, extending outside of the standard survey area.

The 2013 catch was primarily age 2 and age 3 fish (55% of catch by number), with age 5+ fish also contributing a large proportion of the catch (34% of catch by number). Similarly, the majority of the 2014 catch was primarily age 2 and age 3 fish (59% of catch, by number), with age 5+ fish also contributing a little less but still a large portion of the catch (29% of catch by number). The mean age of the acoustic catch at age decreased from 5.1 in 2012 to 4.8 in 2013, increasing to 5.0 years in 2014. The acoustic catch at age is higher than the mean age in the catch in both 2013 and 2014 indicating that older fish are collected in acoustic samples than in the catch. In comparison to the relative exploitation rate in 2012 (10%), the relative exploitation rate increased in 2013 (14%) and then decreased near to the 2012 level in 2014 (11%). The relative exploitation rate varied in response to fluctuating survey biomass in Scots Bay, and the historic high 2014 SSB in Scots Bay has caused the relative exploitation rate to decrease. There has been a trend of declining mean-weight at age. Declining trends in mean-weight at age since the 1970s have reduced productivity of the stock. German Bank is a cause for concern as the spawning biomass estimate has decreased at an average annual rate of 8% since 2011. Historically German Bank is the main spawning area.

The overall biomass estimate was below the LRP by 8% in 2013, but returned above the LRP in 2014 by 25%. The three-year moving average increased above the limit reference point in 2011 and changed very little in 2012. Since 2012, the three-year moving biomass average has been increasing slightly each year (Figure 36A). Overall, there were some positive signs from the fishery in 2013 and 2014 and some of the conservation objectives appear to have been met (Table 25).

OTHER CONSIDERATIONS

Observer reports of by-catch in purse seine sets have reported low numbers of non-herring species, most of which are released unharmed. Observers were present on purse seine gear trips in 4X in both 2013 (7 trips) and 2014 (9 trips). In 2013, observer reports indicated no by-catch of non-herring species in the purse seine sets. In 2014, by-catch from mid-water trawl for herring consisted of small amounts of Silver Hake, Mackerel (Atlantic), Porbeagle Shark, Spiny Dogfish, American Lobster, and a single Bluefin Tuna. All by-catch was released with the exception of very small quantities of Silver Hake, Mackerel (Atlantic), and Spiny Dogfish (Appendix A).

OFFSHORE SCOTIAN SHELF BANKS SPAWNING COMPONENT

There continues to be little information on stock size, distribution, and spawning behavior for the offshore component of the fishery, which currently supports a limited spring fishery on feeding herring. Recent information comes primarily from sampling of this fishery, as well as catches and samples from the summer research bottom trawl survey. There is no information on spawning timing or location for the offshore component of the fishery; however, spawning is presumed to occur in the fall based on the reproductive condition of sampled fish. There was no acoustic survey completed for the offshore area in 2013 and 2014. During the fall of 2014,

however, industry conducted searches for herring aggregations, but failed to find spawning schools.

THE FISHERY

From 1963-1973, foreign fishing boats are estimated to have removed an average of 28,000t of herring per year (with a maximum of 121,000t in 1969) from the Offshore Scotian Shelf banks (Stephenson et al. 1987). Few herring were caught after the extension of jurisdiction in 1977 until 1996, when a fishery was initiated by the Scotia-Fundy purse seine fleet, and 11,700t were taken (Table 3). Since 1996, a fishery has occurred on feeding aggregations on the offshore banks, primarily in May and June, with landings ranging from 58t to 20,261t (Figure 37). The variability in catch levels is often due to problems of fish being too deep, weather, and market conditions, rather than a lack of herring abundance in these areas.

At-sea fishery observers were present on two purse seine gear trips to 'The Patch' area (4W) in 2013. In 2014, observers were also present on two trips (one trip to the Emerald Bank area and one trip to the Cow Pen area) to the 4W area by the *Morning Star* conducting mid-water trawls. There was no recorded by-catch in 2013. In 2014, the mid water trawl by-catch consisted of small amounts of Atlantic Cod, Haddock, jellyfishes, Silver Hake, Butterfish, Snow Crab (Queen), Squirrel or Red Hake and Squid, all of which were released (Appendix A).

In 2013, the landings were below average (6,988t since 1996) at 1,515t, up from the 1,255t in 2012. Most landings (1,466t) were caught by purse seine gear in May-June, in the vicinity of 'The Patch' (Table 1A; Figure 38A). Additional by-catch (47t) was reported from otter trawl fisheries for groundfish and Silver Hake on the Scotian Shelf. A reported 2t of herring was also caught via hand line in September of 2013. The age composition of the catch was primarily adult herring (age 3+) with larger proportions at age 5 (25%), age 6 (27%) and age 7 (18%; Table 26A; Figure 39A).

In 2014, the landings were well below average (6,988t since 1996) at 58t, down from the 1,515t in 2013. The majority of landings (35t) were reported as by-catch from otter trawl fisheries for groundfish and Silver Hake on the Scotian Shelf. An additional 23t were caught by purse seine gear in May, in the vicinity of 'The Patch' (Table 1B; Figure 38B). The age composition of the catch was primarily adult herring with 23% age 3, 15% ages 4 and 5 respectively, 23% age 6 and 14% age 7 (Table 26B; Figure 39B).

RESEARCH AND INDUSTRY SURVEYS

Industry Surveys

No industry survey was conducted in the Offshore Scotian Shelf area in 2013 or 2014. Industry, however, conducted searches for herring aggregations during the fall of 2014 but failed to find spawning schools.

July Bottom Trawl Survey

In recent years, summer research bottom trawl surveys have indicated a relatively widespread herring distribution on the Scotian Shelf (Power et al. 2013; Singh et al. 2014a). There are several shortcomings to using bottom trawl data as an overall abundance for a schooling pelagic species like herring. The bottom trawl data, while useful for documenting size, maturity, and distribution, are not considered indicative of overall herring abundance (Power et al. 2013). Table 27 presents herring abundances from 1970-2014 summer bottom trawl surveys. The trawl survey abundance has remained relatively constant since 2011, as the mean number per tow was 71 in 2011, 108 in 2012, 98 in 2013, and 91 in 2014. Figure 40 presents herring catches from the 2005-2014 DFO summer bottom trawl surveys. Figure 41 presents the 2003-2014

herring size distribution from the summer bottom trawl research survey for the entire 4VWX area. Herring abundance (number per tow) in the summer bottom trawl research survey decreased in the Bay of Fundy from 139 in 2012 to 122 in 2013 and decreased again in 2014 to 96. The overall 4VWX area showed an increase in abundance by number from 83 in 2012 to 98 in 2013. This was followed by a subsequent decrease to 67 in 2014 (Table 27).

OUTLOOK AND MANAGEMENT CONSIDERATIONS

The industry has been encouraged to explore and undertake structured surveys of the offshore area. Industry and DFO continue to work together to improve the biological basis for management. In the absence of recent information on stock status, there is no basis for evaluating the current 12,000t catch allocation, as described in the fishing plan (DFO 2003b).

COASTAL (SOUTH SHORE, EASTERN SHORE AND CAPE BRETON) NOVA SCOTIA SPAWNING COMPONENT

There is no quota for the coastal Nova Scotia spawning component and, apart from three areas, the size and historical performance of spawning groups are poorly documented. A fourth area, the Bras d'Or Lakes, has had no research or surveys for herring since 2000, and this fishery remains closed. Since 1996, the inshore gillnet roe fisheries off Glace Bay, East of Halifax and Little Hope have developed, participants have contributed to sampling and surveying, and the fisheries have attempted to follow the 'survey, assess, then fish' protocol. In addition to the traditional bait and personal-use fisheries, directed roe fisheries have occurred on several spawning grounds since the 1990s (Clark et al. 1999).

THE FISHERY AND RESOURCE STATUS

The landings in the gillnet roe fisheries along the coast of Nova Scotia increased from 2,956t in 2012 to 3,892t in 2013 and continued to increase in 2014 to 4,760t (Table 28 – Part A).

Little Hope/Port Mouton

The 2013 herring gillnet fishery in Little Hope/Port Mouton area extended from June 1st to October 31st. Total landings increased to 2,499t in 2013 from 2,150t in 2012 (Table 28 – Part A; Figure 42A). The catches occurred in three main areas: east of Port Mouton; southeast of Port Mouton; and east of Liverpool (Figure 42A). The 2014 herring gillnet fishery in Little Hope/Port Mouton area similarly lasted from May 31st to October 31st, 2014. The total landings increased again to 3,596t in 2014. Unlike 2013, the catches occurred in one main area, east of Port Mouton, and only minimal catches occurred southeast of Port Mouton and east of Liverpool (Figure 42B).

In 2013, four acoustics surveys were conducted in the Little Hope/Port Mouton area between September 19th and October 21st. The total spawning biomass for the Little Hope area for 2013 was taken as the sum of the four surveys. The total spawning biomass estimate was 74,532t, which is a substantial increase in the spawning biomass estimate over the four year low in 2012 of 12,756t. In 2014, there were four acoustics surveys conducted in the Little Hope/Port Mouton area between September 20th and October 6th. The surveyed biomass in the Little Hope/Port Mouton area decreased to 46,077t, which is approximately 28,000t less than in 2013, but is still above the five-year average of 37,664t (Table 28 - Part B; Figure 43).

In 2013 and 2014, the age composition of the gillnet catch for the Little Hope/Port Mouton area was primarily adult herring, with a substantial proportion (99%, 2013 and 97%, 2014) at age 4 and older (Tables 29A and 29B; Figures 47A and 47B).

East of Halifax (4W Eastern Shore)

Landings increased from 799t in 2012 to 1,390t in 2013 in the Eastern Shore area. The 2013 herring gillnet fishery in the Eastern Shore fishing area began on September 24th and ended on October 11th. Once again, this was primarily a herring roe fishery with catches reported from four main cluster areas: two areas near Halifax Harbour approaches (one south and one southeast) and two southwest of Jeddore Head (Table 28 - Part A; Figures 44A and 45). In 2014, the total landings decreased slightly to 1,163t with the majority of the catch occurring between October 5th and October 9th. Similar to 2013, the catches occurred primarily southwest of Jeddore Head and in a pair of clusters south and southeast of Halifax Harbour (Table 28 - Part A; Figures 44B and 45).

There were four and six acoustic surveys in the Halifax/Eastern Shore area in 2013 and 2014, respectively. Only one of the surveys in 2013 was supported by multi-panel gillnet deployment to collect representative samples of herring being surveyed. In 2014, there was a vast improvement, as six multi-panel gillnet samples were collected in support of the six acoustic surveys. The total spawning biomass for the Eastern Shore area for 2013 was taken as the sum of the four surveys. The total spawning biomass estimate was 6,870t in 2013, which represents an increase over the historic low estimate in 2012 of 3,668t. The estimated total spawning biomass increased again in 2014 to 9,586t, which is near the five-year average of 10,664, but well below the long-term average of 1998 to 2014 of 28,857t (Table 28 – Part B; Figure 45).

In 2013 and 2014, the age composition of the gillnet catch for the Halifax/Eastern Shore area was primarily adult herring, with a substantial proportion (99%, 2013 and 97%, 2014) at age 4 and older (Tables 29A and 29B; Figures 47A and 47B).

Glace Bay

The landings reported in 2013 for the Glace Bay area were only 2t, which is a decrease from 2012 when 7t were landed. In 2014, the total landings decreased further to 1t. There has not been a significant fishery in this area since 2006 when the landings were equal to 85t (Table 28 - Part A; Figure 46). Survey coverage for the Glace Bay area was poor in 2013 with only one survey on September 11th. Few spawning herring were documented in 2013 with an estimated biomass for the area at 50t (Figure 46). The total spawning biomass for the Glace Bay area for 2013 is in close agreement with the trend in landings since 2006 when the SSB was 500t. There were no surveys completed in 2014 (Table 28 - Part A; Figure 46).

Bras d'Or Lakes

This fishery remained closed. No sampling or acoustic surveys have been undertaken in the Bras d'Or lakes to document the size distribution or abundance of herring since 2000. It has been noted since 1997 that the status of herring in the Bras d'Or Lakes is cause for concern. With no sampling or acoustic surveys in recent years, there is no evidence to support any change. Therefore, it is appropriate to reiterate, from a biological perspective, that no fishing should take place on this spawning component.

Age Composition

The age composition of the catch from the fishery for the overall coastal Nova Scotia spawning component in percentage numbers was primarily adult herring age 4 and older, 98% in 2013 and 97% in 2014 (Tables 30A and 30B; Figures 47A and 47B). The mean age of the catch decreased in 2014 to 5.93 from 6.62 in 2013. Appendix B shows the 2013 and 2014 ageing agreement testing between the primary ager and self on a random selection of all survey and commercial otoliths.

OUTLOOK AND MANAGEMENT CONSIDERATIONS

Management approaches and recent research efforts have improved knowledge in three areas (Little Hope/Port Mouton, Halifax/Eastern Shore and Glace Bay), but there has been no information for any adjacent areas. The sporadic surveying in the Glace Bay area mean that no biomass estimates can be identified for the area. The survey method used to estimate abundance in the coastal component differed from that used in SWNS/BoF (Melvin and Power 1999). One difference is the way in which surveys were included, excluded, or combined, which may overestimate abundance.

Individual spawning groups within the entire coastal component are considered vulnerable to fishing because of their relatively small size and proximity to shore. It has been recommended that no coastal spawning area experience a large effort increase in new areas until enough information is available to evaluate the status of the new group.

Since 1997, the status of herring in the Bras d'Or Lakes has been recognized as cause for concern. Since there has been no research or surveys in recent years, it is appropriate to reiterate that no fishing should take place on this spawning component.

The main areas for Little Hope/Port Mouton and Halifax/Eastern Shore use 10% of a five-year rolling average of surveyed acoustic biomass to set annual removals. It is recommended that despite the recent increases in survey biomass from year-to-year, the "survey, assess, then fish" protocol using the five-year average should be adhered to.

SOUTHWEST NEW BRUNSWICK MIGRANT JUVENILES

For over a century, the SWNB weir and shutoff fisheries have relied on the aggregation of large numbers of juvenile herring (ages 1-3) near shore at the mouth of the Bay of Fundy. These fish have been considered to be a mixture of juveniles, dominated by those originating from NAFO Subarea 5 spawning components and have, therefore, been excluded from the 4WX quota.

The success of this passive fishery is historically unpredictable, and the landings time series for this fishery may not be indicative of abundance because catches are extremely susceptible to many factors in addition to abundance, including effort. The number and distribution of active weirs have decreased over the past decade, due in part to the conversion of sites to aquaculture, as well as reduced landings in the past 30 years in the Passamaquoddy Bay area (Table 11). Figures 48A and 48B present the locations of the New Brunswick weirs and the corresponding landings for the 2013 and 2014 fishing seasons. Table 30 shows the monthly herring weir landings weirs from 1978 to 2014.

Landings in the New Brunswick weir and shut-off fishery increased from the historic low in 2012 of 504t to 6,431t in 2013. In 2014, landings decreased to 2,149t, the second lowest since 1963. It is notable that in 2007 landings were 30,944t, the highest in nearly 20 years and higher than the long term average of 21,752t (Table 3; Figure 49). The age distribution of fish caught in the New Brunswick weir and shutoff fishery were mostly juveniles, which are well suited to the sardine market, with 93% at either age 1 or age 2 in 2013 (Table 31A, Figure 50A) and 96% at either age 1 or age 2 in 2014 (Table 31B; Figure 50B). The number of weirs with catches (number of active weirs) increased in the 2013 to 49 from the historic low of 4 in 2012. The number of weirs with catches decreased in 2014 to 26 (Table 11). The primary sources of information for assessing this component are the landings, which have declined markedly from the 1980s to present.

5Z GEORGES BANK

The activities of mid-water trawlers and herring purse seiners on the Canadian portion of Georges Bank (area 5Z) are monitored using the Vessel Monitoring System, and there were no trips to the area and no reported landings in 2013 and 2014.

ACKNOWLEDGEMENTS

The authors would like to thank the following for their invaluable contributions to the provision of survey data and other assistance in the preparation of this report: Atlantic Herring Co-Op; Cape Breeze Seafoods; Comeau's Sea Foods Ltd.; Connors Bros. Ltd.; Herring Science Council; Eastern Shore Fishermen's Protective Association; Fundy Weir Fishermen's Association; Glace Bay herring gillnet group; Little Hope Management Committee; Yarmouth Herring Management Committee; Scotia Garden Seafood Inc.; and South-West Seiners.

^Annual landings by purse seiners are defined for the period from October 15 of the preceding year to October 14 of the current year.
*Adjusted totals include misreporting adjustments for 1978-84 (Mace 1985) and for 1985-93 (Stephenson 1993; Stephenson et al. 1994).
All landings by other gear types are for the calendar year.

Table 4A. Herring purse seine landings (t) by fishing ground areas (as identified from the 10-mile boxes shown in Figure 4) from 1985-2014 for the 4WX stock component. Note that the German Bank fishing ground area used in these tables is not the same as the catch box used to define the German Bank acoustic survey box used in Table 7.

Table 9. Summary of 1998-2014 Spectacle Buoy and Trinity Ledge herring gillnet landings (t) with start and end dates, acoustic survey biomass estimates (t), and overall gillnet landings (t) reported from the area. Shaded cells refer to SSB estimates calculated without the CIF. Bold-outlined cell indicates that in 2002 the exploitation rate exceeded 100%. A dash (-) indicates no data; 'n/s' indicates no survey.

CPUE - catch per unit effort.

Table 13. Summary of the minimum observed SSB for each of the surveyed spawning grounds in the SWNS/BoF component of the 4WX stock complex. Total SSB is rounded to nearest 100t (except 2013 and 2014) and all data was calculated with the use of the CIF (Singh et al. 2014a). Shaded rows = sub-totals and totals. A dash (-) indicates no data; 'n/s' indicates no survey.

Table 15B. Summary of biological samples by gear and month as collected during the 2014 4VWX herring fisheries. '# LF Samples' is the number of length frequency samples collected, '# Measured' is the number of lengths taken, and '# Processed' is the number of detail fish with sex and maturity determined.

Table 22. Average (fishery weighted) weights at age (g) for the SWNS/BoF component of the 4WX herring fishery for 1965-2014. Data for 1965-1967 and 1979-1983 are averages for the period 1968-1978. Note: years 1965-1967 (except age 11 for 1967)and 1979-1983 have average weights for 1967-2000 applied.

Table 25. Observations and conclusions on conservation objective elements from the management plan for SWNS/BoF spawning component in 2013 and 2014.

Objective	**2013 and 2014: Observations**
Persistence of all spawning components	Spawning was observed in the Scots Bay and German Bank areas. Spawning activity could not be determined on Seal Island or Browns due to a lack of fishing or survey effort. Trinity Ledge again had minimal spawning.
Maintain biomass of each component	Although there is uncertainty associated with the biomass estimates, longer-term trends in biomass appear to be evident for the SW Nova Scotia/Bay of Fundy spawning component: a decreasing trend in the German Bank area from 1999 to present and an increasing trend in the Scots Bay area since 2005. The biomass of spawning fish estimated to be on Trinity Ledge from 2012 to 2014 is low relative to values observed in the early 2000s.
Maintain broad age composition	There is currently a broad range of ages in the commercial landings (1-11), as well as in the acoustic survey catch at age (1-11). In 2013 and 2014, the proportion of the catch older than age 5 was 21% and 22% (by numbers) respectively, which is the 2nd and 3rd highest proportion of age 5+ caught since 1994.
Maintain long spawning period	Start of spawning in 2013 and 2014 for Scots Bay was earlier than previously recorded based on acoustic survey results since 1999. Spawning in the German Bank area appeared to start about the same time in both years and in agreement with the previous five years but displays a trend of an earlier end date. Therefore, there appear to be slight changes in the spawning periods on the two major spawning grounds. Minimal spawning occurred on Trinity Ledge.
Fishing mortality at or below $F_{0.1}$	Fishing mortality could not be determined. Relative exploitation rates based on acoustic SSB and landings increased slightly in 2013 and then decreased near to the 2012 level in 2014.
Maintain spatial and temporal diversity of spawning	Spawning in the German Bank area displays a trend of an earlier end date. Spatially, the German Bank area had a similar distribution to previous years, extending slightly further south in 2013 than previous years. Duration of spawning in Scots Bay was extended slightly in comparison to previous years as earlier start dates occurred. Spatially, the Scots Bay area had a wider distribution than in previous years, extending throughout the strata box. Therefore, spawning periods are being maintained both temporally and spatially on the two major spawning grounds Trinity Ledge spawning is very restricted in space and time.
Maintain biomass at moderate to high levels	Biomass estimates have fluctuated about the LRP since 2010. Confidence intervals include the LRP in three of the last four years the exception being 2012 when the confidence interval was above the LRP.
Maintain three-year moving average above the lower reference point	The three-year moving average increased above the LRP in 2011 and changed very little in 2012. Since 2012, the three-year moving biomass average has been increasing slightly each year.

Table 28. Coastal Nova Scotia spawning component summary of A) herring landings (t) from gillnet fisheries 1996-2014, B) spawning biomass (t) from acoustic surveys in the Coastal Nova Scotia spawning component from 1996-2014, and C) estimated exploitation as calculated as landings/ SSB (%). Note that shaded cells include mapping surveys that estimated biomass based on visual sounder estimates. Data prior to 2003 calculated with the CIF are not available and estimates of exploitation were not made for these years. A dash (-) indicates no data; n/a indicates not applicable; 'n/s' indicates no survey.

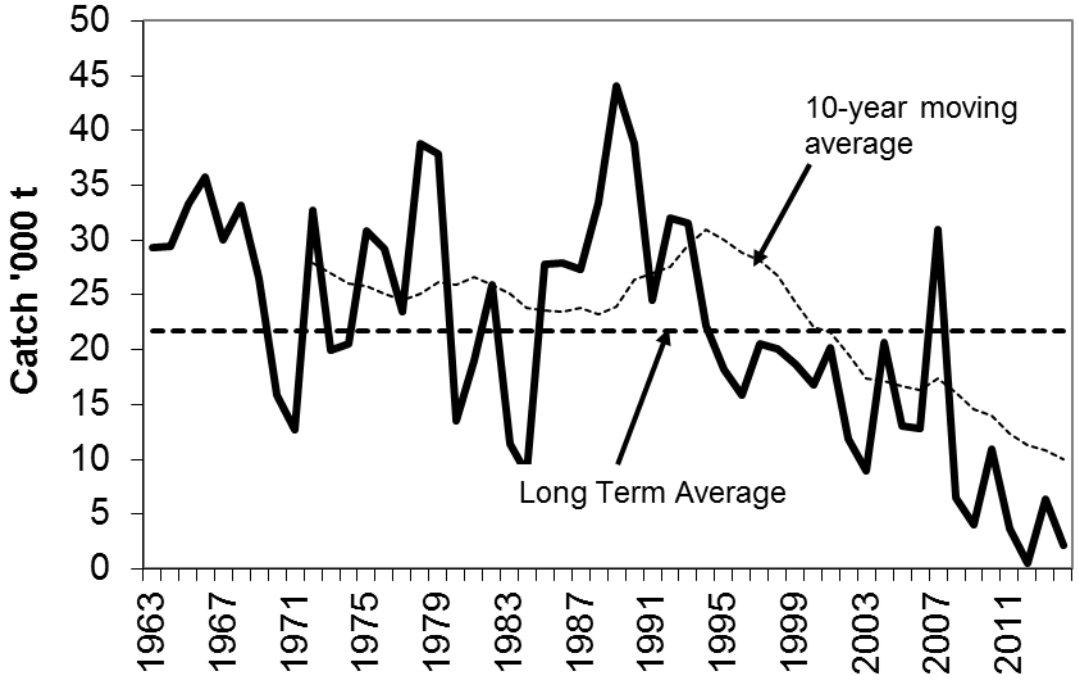

Figure 49. Herring landings ('000t) from the SWNB weir and shutoff fishery for 1963-2014 with long term average and 10-year moving average.

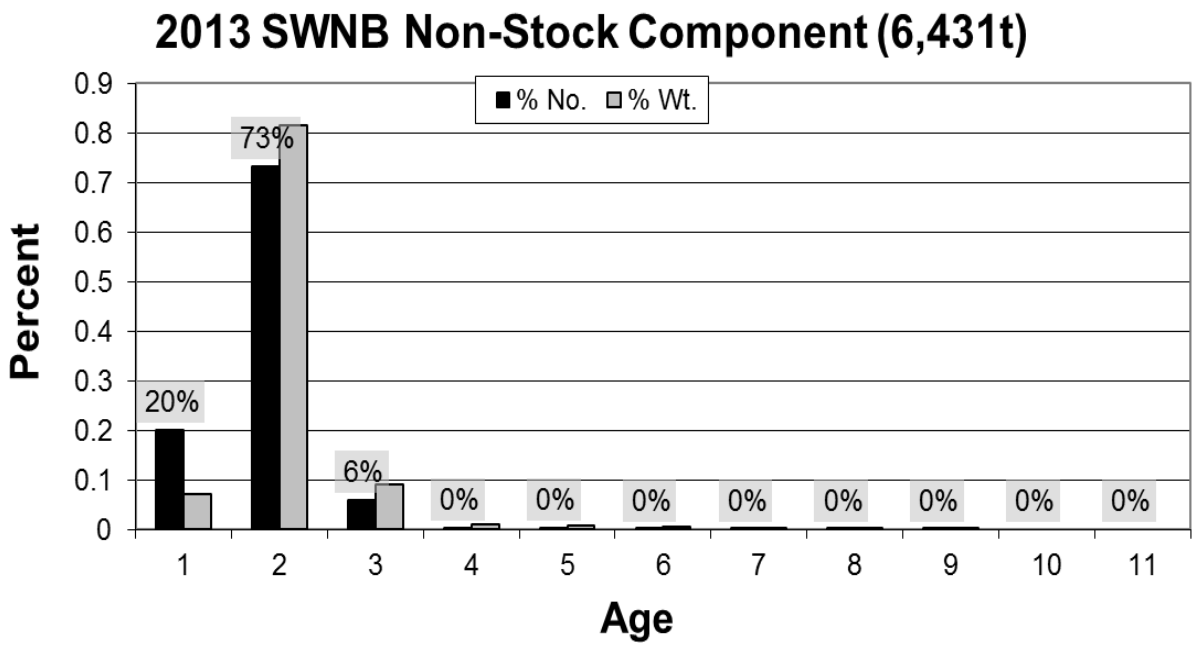

Figure 50A. Fishery catch at age (% numbers and % weight) for the 2013 SWNB migrant juvenile herring component.

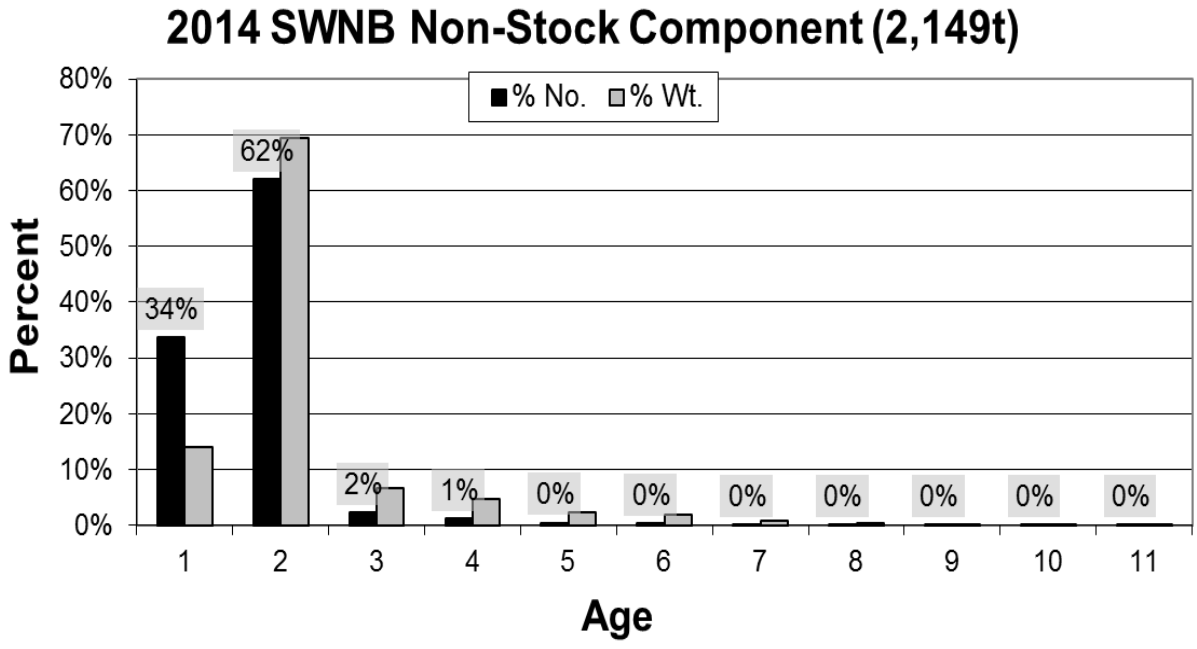

Figure 50B. Fishery catch at age (% numbers and % weight) for the 2014 SWNB migrant juvenile herring component.

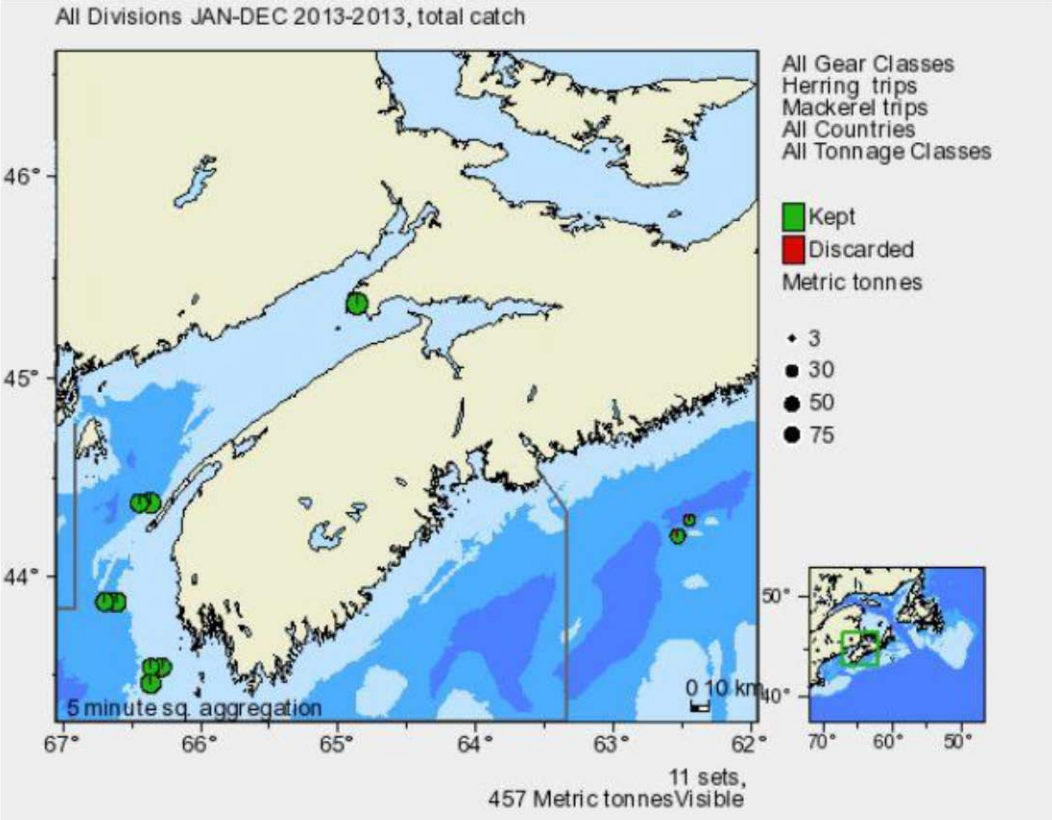
APPENDICES

APPENDIX A: OBSERVER REPORTS FOR HERRING DIRECTED TRIPS FROM 2012-2013 AND 2013-2014

2013 Observer data:

- 9 trips, 11 sets monitored, purse seine gear only
- 2 trips in area 4W (Patch area) in June and rest in 4X during July/August
- Only herring caught

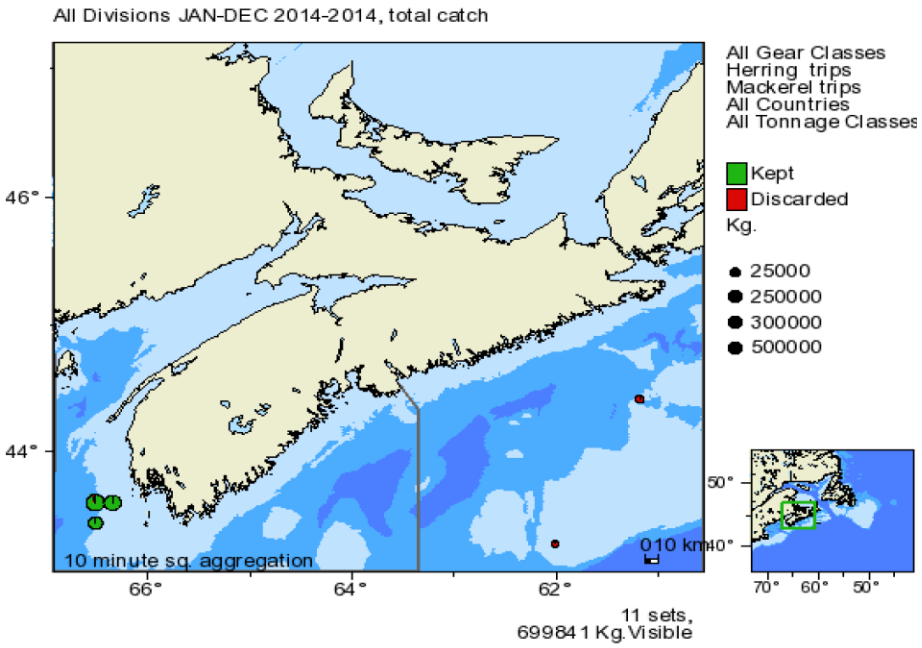


Catch Composition (Metric tonnes)		
Species	Kept 2013	Discarded 2013
HERRING(ATLANTIC)	456.909	0.054

Figure A1. Species report for 2013 herring and mackerel trips combined.

2014 Observer data:

- 11 trips (14 sets) monitored; purse seine gear and mid-water trawl.
- 9 trips (12 sets) in area 4X in July to October using purse seine gear only.
- 2 trips (2 sets) in area 4W in October/November conducting mid-water trawl.
- By-catch of small amounts of porbeagle – mackerel shark, haddock, jellyfishes, squirrel or red hake, squid (NS), snow crab (queen), cod (Atlantic), butterfish and American lobster were released.
- By-catch of silver hake, mackerel (Atlantic), and spiny dogfish were kept.



Catch Composition (Metric tonnes)
