ASSESSMENT OF SNOW CRAB (CHIONOECETES OPILIO) IN THE SOUTHERN GULF OF ST. LAWRENCE (AREAS 12, 19, 12E AND 12F) TO 2017 AND ADVICE FOR THE 2018 FISHERY

Snow crab (Chionoecetes opilio).

Figure 1. Map of the southern Gulf of St. Lawrence showing the Crab Fishing Areas (CFAs), fishing grounds and management buffer zones (shaded area). Fishing grounds are labeled as follows: 1 Chaleur Bay, 2 Shediac Valley, 3 Orphan Bank, 4 Bradelle Bank, 5 Magdalen Channel, 6 Cape Breton Corridor, 7 Laurentian Channel, and 8 American Bank.

Context:

Snow crab, Chionoecetes opilio, has been commercially exploited in the southern Gulf of St. Lawrence since the mid-1960s. There are four individually managed fishing areas among which Area 12 (Figure 1) is the largest fishery in terms of its fishable surface, number of participants and landings. In Areas 12, 12E and 12F, the fishing season generally starts in April-May as soon as the Gulf is clear of ice and continues into early summer while in Area 19, the fishery opens after June 30 and usually ends in mid-September. The landing of females is prohibited and only hard-shelled males ≥ 95 mm of carapace width are commercially exploited.

DFO Gulf Region Fisheries and Aquaculture Management requested an assessment of the resource status in 2017 and catch advice for the 2018 fishery. This document provides an overview of the assessment results and the science advice. Catch rates and other fishery performance indicators are reported. The assessment of the status of the southern Gulf snow crab resource (Areas 12, 19, 12E and 12F) is based on fishery independent trawl surveys that provide indicators of: abundance (commercial biomass), reproductive potential (abundance of mature females), and recruitment. A science peer review meeting was conducted January 24-25, 2018 in Moncton, NB. Participants at the science review were from DFO Science, DFO Fisheries Management, fishing industry, Aboriginal organizations, external reviewers and provincial governments.

SUMMARY

- Snow crab in the southern Gulf of St. Lawrence is considered as a single stock unit for assessment purposes. This stock unit comprises of fishing areas 12, 19, 12E, and 12F.
- The landings of snow crab from the southern Gulf of St. Lawrence in 2017 were 43,656 t from a revised quota of 43,475 t.
- The resulting exploitation rate of the 2017 fishery in the southern Gulf of St. Lawrence was estimated at 44%.
- The 2017 post-fishery survey biomass of commercial-sized adult male crabs was estimated at 66,021 t (95% confidence interval of 57,456 to 75,495 t), a decrease of 33.4% from 2016. The available biomass for the 2018 fishery, derived from the 2017 survey, is within the healthy zone of the Precautionary Approach (PA) framework.
- Total commercial biomass in the 2017 survey was composed 78% of new recruitment (51,262 t) and 22% of residual biomass (14,759 t). The recruitment to the commercial biomass decreased by 31% relative to the previous year.
- Based on the agreed harvest decision rule which has been assessed as compliant with the PA, the point estimate of the biomass in the 2017 survey of 66,021 t corresponds to an exploitation rate of 38.3% and a Total Allowable Catch (TAC) of 25,286 t for the 2018 fishery.
- The risk analysis indicates that the 2018 TAC derived from the harvest decision rule would result in a near 100% chance of the biomass for the 2019 fishery being above B_{USR} and in the healthy zone of the PA.

Fishery performance in 2017 in Area 12

- The 2017 landings in Area 12 were 39,825 t from a revised quota of 39,651 t.
- The CPUE (expressed as kg per trap haul (kg/th)) in 2017 (72.0 kg/th) increased compared to 2016 (64.0 kg/th).
- The incidence of soft-shelled crab in 2017 (6.0%) was comparable to 2016 (5.3%).

Fishery performance in 2017 in Area 19

- The 2017 landings in Area 19 were 2,944 t from a revised quota of 2,945 t.
- The CPUE in 2017 (142.8 kg/th) was comparable to 2016 (142.5 kg/th).
- The incidence of white-crab increased from 8.2% in 2016 to 11.6% in 2017.

Fishery performance in 2017 in Area 12E

- In Area 12E, the landings were 203 t from a revised quota of 199 t.
- The CPUE in 2017 (60.9 kg/th) increased compared to 2016 (51.5 kg/th).
- The incidence of soft-shelled crab in 2017 remained low, at 2.0% compared to 1.1% in 2016.

Fishery performance in 2017 in Area 12F

- The 2017 landings in Area 12F were 684 t from a revised quota of 680 t.
- The CPUE in 2017 (72.6 kg/th) increased compared to 2016 (43.9 kg/th).
- The incidence of soft-shelled crab decreased from 10.4% in 2016 to 1.9% in 2017.

BACKGROUND

Species Biology

Snow crab (*Chionoecetes opilio*) is a crustacean, like lobster and shrimp, but with a flat, almost circular body and five pairs of spider-like legs. The hard outer shell is periodically shed in a process called molting. After molting, crabs have a soft shell for a period of 8 to 10 months. Soft-shelled crab is defined by shell hardness (<68 durometer units) and includes both new-soft (condition 1) and clean hard-shelled crab (condition 2). The term white-crab is used in the summer fishery of Area 19 because the newly-molted crabs have reached a relatively harder carapace than those observed during the spring fishery (Areas 12, 12E and 12F). White crab is defined by shell hardness <78 durometer units and includes both new soft (condition 1) and clean hard-shelled crab.

Unlike lobsters, snow crabs do not continue to molt throughout their lives. Females stop growing when they acquire a wide abdomen for carrying eggs, which occurs at carapace widths (CW) less than 95 mm. Males stop growing when they acquire large claws on the first pair of legs, which can occur at CWs between 40 and 150 mm. Females produce eggs that are carried beneath the abdomen for approximately two years in the southern Gulf of St. Lawrence. The eggs hatch in late spring or early summer and the newly-hatched crab larvae spend 12-15 weeks in the water column. At the end of this period, they settle on the bottom. It takes at least 8-9 years (post-settlement) for males to reach legal commercial size.

Fishery

Until 1994, the snow crab fishery in Area 12 (Figure 1) involved 130 mid-shore crab harvesters from New Brunswick, Quebec, and Nova Scotia. Since 1997, the PEI coastal fishery, (formerly Areas 25/26) has been integrated into Area 12. In 2003, a portion of the coastal fishery off Cape Breton (formerly Area 18) was also integrated into Area 12. For the purpose of this assessment, Area 12 refers to the management unit that includes snow crab fishing zones 12, 18, 25, and 26 (as defined in regulation) (Figure 1). The number of allocation shares in Area 12 was 251 in 2017.

In 1978, Area 19 (Figure 1) was established for the exclusive use of Cape Breton inshore fish harvesters with vessels less than 13.7 m (45 feet) in length. There were 158 allocation shares in Area 19 in 2017.

Areas 12E and 12F were introduced in 1995 as exploratory fisheries. In 2002, the status of Areas 12E and 12F was changed from exploratory to commercial fishing areas. There were four snow crab allocation shares in Area 12E (from New Brunswick, PEI, and Quebec) and 46 snow crab allocation shares in Area 12F (from Nova Scotia and Quebec) in 2017.

The minimum legal carapace width for males is 95 mm, females are not harvested and soft-shell and white crab are not targeted by the fishery. Baited traps, constructed of wire or tubular steel, are used to catch crab, mainly on mud or sand-mud bottoms at temperatures ranging from -1 to 4.5°C, and depths ranging from 50 to 280 m. The fishery takes place from spring to early summer in Areas 12, 12E and 12F and after June 30 in Area 19.

Management of these fisheries is based on quotas and effort controls (trap allocations, trap dimensions, and seasons). There are at-sea soft-shelled and white crab catch monitoring protocols which allow for closure of portions of each fishing area when the proportion of the catch of males of these carapace conditions exceeds 20%. The protocols are in place to maximize the yield and the reproductive potential of the resource.

Table 1. Number of allocation shares, vessels, traps, revised quotas, opening dates, and dates of the last landing of the snow crab fishery by management area in the southern Gulf of St. Lawrence in 2017.

Characteristics	Area 12	Area 12E	Area 12F	Area 19	Southern Gulf
Allocation shares ^a	251	4	46	158	459
Number of active vessels	354	4	18	107	483
Total number of traps allowed	46,622 ^b	475	1,640 ^c	1,732	50,469
Opening date	April 25	April 20	April 19	July 13	-
Date of the last landing	July 24	June 22	June 15	August 5	-
Revised quota (t) ^d	39,651	199	680	2,945	43,475 ^e
Landings (t)	39,825	203	684	2,944	43,656

^a The number of quota allocations among which the Total Allowable Catch is divided (Source: DFO Administrative List for Snow Crab Areas 12, 12E, 12F, and 19).

^b The total number of authorized traps in Area 12 was higher in 2017 than 2016, due to an increase in traps for the midshore traditional fleet. Additionally, the increase in the 2017 TAC resulted in an increase in the number of authorized traps for groups who designate operators (i.e. more vessels on the water). ^c The increased number of traps in 2017 was the result of an arrangement to increase the total allocation shares in Area 12F when the TAC is higher than 544 t.

^d For reasons of interannual quota adjustments, reconciliations, and re-distribution of the scientific quota among areas, the revised quota does not necessarily correspond to the TAC in the notice to harvesters. ^e Quota includes 495 t set aside to finance the trawl survey in 2017 (under Section 10 of the Fisheries Act).

The landings from the southern Gulf of St. Lawrence were low in the 1970s and increased with four periods of high landings: 1981-1986, 1994-1995, 2002-2009, and more recently 2012 to 2017 (Figure 2). The landings of snow crab from the southern Gulf of St. Lawrence in 2017 were 43,656 t from a revised quota of 43,475 t. The landings in the southern Gulf in 2017 represent the highest of the history of this fishery.

The 2017 fishing season in Area 12 opened on April 25 and the last landings were recorded on July 24 with reported landings of 39,825 t from a revised quota of 39,651 t (Tables 1 and 2; Figure 2). In accordance with the soft-shelled crab protocol, 57 of 323 grids, which include the closure of the sector 1 (Chaleur Bay) on July 4, were closed during the 2017 fishing season. The fishing effort estimated from logbooks has varied from 161,148 to 553,125 trap hauls between 1987 and 2017, with the lowest effort in 2010 and the highest effort in 2017. The fishing effort was 553,125 trap hauls in 2017, an increase from 2016 (304,624 trap hauls) (Table 2).

Table 2. Revised quota (2012 to 2017), and landings (tonnes), fishing effort (trap hauls) and catch performance for the snow crab fishery in Area 12, 2009 to 2017.

Fishery descriptor	2009	2010	2011	2012	2013	2014	2015	2016	2017
Revised quota (t) ^{1a}	20,900	7,700	8,585	18,143	22,548	19,409	23,021	19,393	39,651
Landings (t	20,896	7,719	8,618	18,159	22,645	19,633	23,080	19,499	39,825
CPUE (kg/trap-haul) ^b	48.2	47.9	53.0	68.0	76.4	61.8	67.9	64.0	72.0
Effort (trap hauls)	433,527	161,148	162,604	267,044	296,398	317,689	339,912	304,624	553,125
Soft-shelled crab (%) in catches ^c	5.0	6.5	6.2	3.7	2.8	4.4	4.9	5.3	6.0
Grids closed (total of 323)	78	74	233	7	5	8	41	5	57

^a For reasons of interannual quota adjustments, reconciliations, and re-distribution of the scientific quota among areas, the revised quota does not necessarily correspond to the TAC in the notice to harvesters.

^b CPUE values are not standardized and do not account for changes in management measures.

^c The percentage is based on a durometer reading of 68. Catches are defined as male crabs of all sizes (commercial >= 95 mm and non-commercial) in traps.

The 2017 fishing season in Area 19 opened on July 13 and the last date of landings was August 5 with reported landings of 2,944 t from a revised quota of 2,945 t (Tables 1 and 3; Figure 2). In accordance with the white crab protocol (shell hardness <72 durometer units), three sectors within Area 19 were closed during the 2017 fishing season. The fishing effort in Area 19 has varied from 11,138 to 56,517 trap hauls between 1987 and 2017, with the lowest effort in 2010 and the highest effort in 2004. The effort in 2017 was 20,616 trap hauls, an increase from 2016 (Table 3).

Table 3. Revised quota (2012 to 2017) and landings (tonnes), fishing effort (trap hauls) and catch performance for the snow crab fishery in Area 19, 2009 to 2017.

Fishery descriptor	2009	2010	2011	2012	2013	2014	2015	2016	2017
Revised quota (t) ^a	2,433	1,360	1,703	2,907	2,654	3,745	2,130	1,701	2,945

Sectors closed ^d	9/9	4/9	0/9	0/9	0/9	0/9	2/9	4/9	3/9

^a For reasons of interannual quota adjustments, reconciliations, and re-distribution of the scientific quota among areas, the revised quota does not necessarily correspond to the TAC in the notice to harvesters.

^b CPUE values are not standardized and do not account for changes in management measures.

^c The percentage is based on a durometer reading of 72. Catches are defined as male crabs of all sizes (commercial >= 95 mm and non-commercial) in traps.

^d Total number of sectors was changed from 4 to 9 sectors in 2009.

The 2017 fishing season in Area 12E began on April 20 and the date of last landings was June 22 with reported landings of 203 t from a revised quota of 199 t (Tables 1 and 4; Figure 2). The fishing effort in Area 12E has varied from 1,825 to 10,074 trap hauls between 1995 and 2017, with the lowest effort in 2010 and the highest effort in 2006. The fishing effort in Area 12E

increased from 2,796 trap hauls in 2016 to 3,333 trap hauls in 2017. In accordance with the soft-shelled protocol, no grids within Area 12E were closed during the 2017 fishing season.

Fishery descriptor	2009	2010	2011	2012	2013	2014	2015	2016	2017
Revised quota (t) ^a	200	67	75	251	204	170	189	144	199
Landings (t)	67	50	76	185	204	178	192	144	203
CPUE (kg/trap-haul) ^b	14.4	27.4	31.5	32.9	40.1	47.3	65.8	51.5	60.9

Soft-shelled crab (%) in catches ^c	7.8	14.7	8.4	3.3	15.9	7.8	9.8	1.1	2.0
Grids closed (total of 8)	2	0	0	0	0	0	0	0	0

Table 4. Revised quota (2012 to 2017) and landings (tonnes), fishing effort (trap hauls) and catch performance for the snow crab fishery in Area 12E, 2009 to 2017.

^a For reasons of interannual quota adjustments, reconciliations, and re-distribution of the scientific quota among areas, the revised quota does not necessarily correspond to the TAC in the notice to harvesters.

^b CPUE values are not standardized and do not account for changes in management measures.

^c The percentage is based on a durometer reading of 68. Catches are defined as male crabs of all sizes (commercial >= 95 mm and non-commercial) in traps.

In Area 12F, the fishery in 2017 opened on April 19 and the last date of recorded landings was June 15 with reported landings of 684 t from a revised quota of 680 t (Tables 1 and 5; Figure 2). The fishing effort in Area 12F has varied from 4,437 to 23,163 trap hauls between 1995 and 2017, with the lowest effort in 2002 and the highest effort in 2014. The fishing effort increased from 8,667 trap hauls in 2016 to 9,421 trap hauls in 2017. In accordance with the soft-shelled protocol, no sector within Area 12F was closed during the 2017 fishing season.

Table 5. Revised quota (2012 to 2017) and landings (tonnes), fishing effort (trap hauls) and catch performance for the snow crab fishery in Area 12F, 2009 to 2017.

Fishery descriptor	2009	2010	2011	2012	2013	2014	2015	2016	2017
Revised quota (t) ^a	465	420	314	706	543	906	516	373	680
Landings (t)	309	420	313	706	543	882	510	381	684
CPUE (kg/trap-haul) ^b	22.0	29.3	32.5	41.8	49.0	38.1	38.2	43.9	72.6
Effort (trap hauls)	14,045	14,335	9,631	16,890	11,086	23,163	13,351	8,667	9,421
Soft-shelled crab (%) in catches ^c	11.4	8.6	2.6	9.4	2.4	1.7	3.3	10.4	1.9
Sectors closed (total of 3)	3	2	0	0	0	0	0	0	0

^a For reasons of interannual quota adjustments, reconciliations, and re-distribution of the scientific quota among areas, the revised quota does not necessarily correspond to the TAC in the notice to harvesters.

^b CPUE values are not standardized and do not account for changes in management measures.

^c The percentage is based on a durometer reading of 68. Catches are defined as male crabs of all sizes (commercial >= 95 mm and non-commercial) in traps.

Catch per unit of effort (CPUE) expressed as kg per trap-haul (kg/th) is calculated directly from logbook data, as the ratio of total landings (kg) to total effort (trap-hauls). CPUE values are not standardized and do not account for changes in management measures and fishing practices and as a result may not be directly proportional to biomass. In Area 12, the annual mean CPUE increased in 2017 (72.0 kg/th) compared to 2016 (Table 2; Figure 3). In Area 19, the CPUE (142.8 kg/th) in 2017 is comparable to 2016 (Table 3; Figure 3). The CPUE in Area 12E increased (60.9 kg/th) in 2017 compared to 2016 while in Area 12F, the CPUE (72.6 kg/th) in 2017 increased compared to 2016 (Tables 4 and 5; Figure 3).

Figure 3. Catch per unit effort (kg per trap haul) in the southern Gulf of St. Lawrence snow crab fishery, Areas 12, 19, 12E and 12F, based on logbooks, 1997 to 2017.

The percentage of soft-shelled crab and white crab is calculated using data collected from the at-sea observer program. The incidence of soft-shelled crab and white crab in catches is strongly influenced by the fishing strategy used by harvesters during the season, as well as the hard-shell commercial-sized adult crab abundance in the area.

The percentage of soft-shelled crab in Area 12 in 2017 was 6.0%, comparable to 2016, and has remained low since 2008 (Table 2). In Area 19, the percentage of white crab was 11.6% in 2017, an increase from 2016 (Table 3). The percentage of soft-shelled crabs in Area 12E in 2017 was 2.0%, comparable to 2016 (Table 4). In Area 12F, the percentage of soft-shelled crabs in 2017 was 1.9%, a decrease from 2016 (Table 5).

ASSESSMENT

Snow crab in the southern Gulf of St. Lawrence is considered as a single stock unit for assessment purposes. This stock unit comprises of fishing areas 12, 19, 12E, and 12F.

The survey design and biomass estimation polygon covers the entire area of the southern Gulf of St. Lawrence defined by the 20 to 200 fathoms depth contours (which approximately corresponds to the areal extent of bottom temperatures < 5 °C which are considered favorable for all life stage of snow crab and encompassing the area of the southern Gulf of St. Lawrence stock unit) (Figure 4). The survey spatial sampling design partitioned this area into square grids of 12.7 km x 12.7 km. In 2017, the number of sampling stations remained at 355. The 346 successful sampling stations from the 2016 trawl survey were used as fixed stations as per the recommendations from the 2014 scientific peer review (DFO 2014a) and a new set of nine sampling stations (one that was abandoned and the 8 sampling stations that were conducted outside their assigned grids in 2016) was generated randomly. A total 353 stations were successfully trawled in 2017; two sampling squares had to be abandoned due to failures to successfully traw the area. The survey was conducted between July 10 and September 22, 2017. All at-sea survey and sampling protocols were identical to previous years.

The survey in 2017 was financed through a collaborative agreement with the fishing industry under Section 10 of the Fisheries Act.

Figure 4. The survey and estimation polygon of 57,840 km² used for the 2017 snow crab stock assessment in the southern Gulf of St. Lawrence (all of the coloured areas) and corresponding estimation polygons for the four crab fishing areas (12, 12E, 12F, and 19). The unassigned zone north of areas 12E and 12F (label A) and buffer zones (labels B and C) are also shown.

Stock Trends and Current Status in the Southern Gulf of St. Lawrence

Interpretation of stock status is based on inferences from abundance data from the snow crab trawl surveys conducted during July to October, over the entire area of snow crab distribution in the southern Gulf of St. Lawrence. The surveys provide estimates of commercial biomass which are comprised of residual biomass (hard-shelled adult males of legal size remaining after the fishery) and recruitment biomass (soft-shelled adult males >= 95 mm CW defined as R-1 that will be available to the fishery the following fishing season). The snow crab trawl survey also provides indices of future male recruitment to the fishery (pre-recruits defined as R-4, R-3 and R-2). The pre-recruits R-4, R-3 and R-2 represent adolescent male crabs with a carapace width range of 56-68, 69-83, and larger than 83 mm, respectively. A portion of these crabs could be available to the fishery in 4, 3 and 2 years, respectively. An index of abundance of small male crabs (34-44 mm CW) is also presented as an indicator of potential long-term recruitment. It takes at least six years for these small male crabs to reach the commercial size of 95 mm CW.

Spawning stock abundance consists of females (pubescent and mature). The term pubescent refers to females that will molt to maturity and mate the following year and become primiparous females (first brood). The term 'multiparous' refers to females which are carrying a brood for the second time or more. The term 'mature females', includes primiparous and multiparous females.

The biomass of commercial-sized adult males in the southern Gulf of St. Lawrence from the 2017 trawl survey was estimated at 66,021 t (95% confidence interval (C.I.) range of 57,456 t to 75,495 t) (Table 6; Figure 5). The 2017 commercial biomass in the southern Gulf decreased by 33.4% relative to the 2016 estimate.

The recruitment to the fishery at the time of the 2017 survey was 51,262 t (95% C.I. 44,154 t to 59,352 t), comprising 78% of the commercial biomass (Table 6; Figure 5). The recruitment to the fishery in 2017 decreased by 31% compared to the 2016 estimate. The residual biomass (carapace conditions 3 to 5) of commercial-sized adult male crabs after the 2017 fishery was estimated at 14,759 t (95% C.I. 12,209 t to 17,683 t), a decrease of 40.7% compared to the 2016 estimate (Table 6; Figure 5).

Figure 5. Total commercial biomass, recruitment commercial biomass, and residual commercial biomass (in 1,000 tonnes; means with 95% confidence intervals) in the southern Gulf of St. Lawrence, 1997 to 2017.

A second fishery independent survey of the southern Gulf of St. Lawrence is used to provide an index of the biomass of commercial-sized adult male crabs. The multi-species research vessel bottom trawl survey (RV), a stratified random design, has been conducted annually in September since the early 1970's although the estimation of commercial-sized adult male crabs biomass is available only since 2001.

Over the available time series, the September multi-species bottom trawl survey index shows generally similar trends (within the estimation precisions of the surveys) for commercial adult male snow crab biomass between 2001 and 2017 as do the estimates from the dedicated snow crab trawl survey (Figure 6). The RV survey index indicated a decrease in the biomass of commercial-sized adult male snow crab in 2017, similar to what was estimated from the dedicated snow crab survey data.

In the 2017 trawl survey, geographic concentrations of commercial-sized adult males were located in Bradelle Bank, in Chaleur Bay, in the southern part of the Magdalen Channel and in the southeastern part of the southern Gulf of St. Lawrence (Figure 7). The spatial distributions of commercial-sized adult males have varied annually during increasing and decreasing phases of the commercial biomass (Figure 8).

Table 6. Total commercial, recruitment, and residual biomass (in tonnes; means with 95 % confidence intervals) of commercial-sized adult male crabs (>= 95 mm carapace width) in the southern Gulf of St. Lawrence, 2007 to 2017.

	Commercial	Recruitment	Residual
Year of the survey	Biomass (t)	Biomass (t)	Biomass (t)
2007	66,660	39,635	27,025

Figure 6. Index of trawlable biomass (in tonnes; means and 95% confidence intervals) of adult male snow crab \geq 95 mm carapace width in the September multi-species research vessel bottom trawl survey for 2001 to 2017 excluding 2003, based on a geographic area comparable to that used for the current snow crab assessment.

Figure 7. Density (kg per km^2) contours of commercial-sized adult male crabs (\geq 95 mm CW) in the southern Gulf of St. Lawrence in 2017, based on the snow crab trawl survey.

Figure 8. Density (kg per km^2) contours of commercial-sized adult male crabs (\geq 95 mm CW) in the southern Gulf of St. Lawrence, 2008 to 2016.

Gulf Region

The exploitation rate in the southern Gulf of St. Lawrence is calculated as the ratio between the catch of the fishery in the year of the assessment and the commercial biomass estimated from the trawl survey in the previous year. The exploitation rates varied between 21% and 45% from 1998 to 2017 (Figure 9). In 2017, the exploitation rate was 44% as expected with the use of the agreed harvest decision rule.

Total mortality is calculated as one minus the proportion of the residual biomass estimated from the survey in the year of the assessment divided by the biomass available to the fishery as estimated in the previous year's survey. In 2017, total mortality was estimated at 85.1% (Figure 9). The total mortality has varied between 45.8% and 82.5% from 1997 to 2016, except for 2011 when it was estimated at 5.6% (Figure 9).

Over the time series, the estimated commercial biomass from the survey was 29.4% higher than the sum of the residual biomass and the landings of the following year. This difference (termed non-fishing directed mortality) and the associated inter-annual variability could be attributed to a number of factors including misattribution of recruitment and residual groups, variability in survey estimates, natural mortality, by-catch mortality, unreported landings, as well as crab movement in and out of the sampling area.

Figure 9. Exploitation rates (means and 95% confidence intervals) by the fishery and total mortality of commercial-sized adult male snow crab in the southern Gulf of St. Lawrence, 1997 to 2017. The 2011 total mortality point is isolated from the series due to uncertainties.

As requested by DFO Fisheries and Aquaculture Management, the 2017 commercial biomass estimates in snow crab fishing areas (12, 19, 12E and 12F), two buffer zones (between Areas 12F and 19, between Areas 12 and 19) and the unassigned zone (north of Areas 12E and 12F), as shown in Figure 4, are summarized in Table 7. The majority of biomass was found in Area 12, followed by Area 19, 12F, 12E, buffer zones, and the unassigned zone (Table 7). Estimating the commercial biomass by fishing areas results in values with larger confidence intervals. This situation of high uncertainty is more pronounced in small fishing areas, as they contain few sampling stations.

Table 7. Estimates of commercial biomass (in tonnes; means and 95% confidence intervals) in 2017 for the southern Gulf of St. Lawrence estimation polygon of 57,840 km² and for each of the snow crab fishing areas 12, 19, 12E, 12F, the buffer zones, and the unassigned zone. Labels refer to those in Figure 4.

	Surface area	Co	mmercial biomass (t)
Area	(km²)	Mean	95% confidence interval
Southern Gulf ^a	57,840	66,021	57,456 – 75,495
Area 12	48,028	54,739	47,253 - 63,068
Area 19	3,833	5,340	3,838 – 7,238
Area 12E	2,443	637	101 – 2,173
Area 12F	2,438	4,657	3,449 – 6,152
Subtotal of crab fishing areas	56,742	65,373	na
Unassigned zone above 12E and 12F (label A)	674	142	7 – 714
Buffer zone 19 / 12F (label B)	112	142	74 - 246
Buffer zone 12 / 19 (label C)	310	395	186 – 740
Total of all individual area estimates ^a	57,838	66,052	na

^a Small difference in the sum of all individual area estimates compared to the southern Gulf estimates is due to rounding of intermediate calculations.

Based on abundances of adolescent males of R-2, R-3 and R-4 from recent surveys, the predicted recruitment of commercial-sized adult male crabs for the 2018 survey, available for the 2019 fishery, was estimated at 47,700 t (95% C.I. 33,800 to 64,880 t) (Figures 10 and 11).

Figure 10. Estimated (black circle symbols are the means with 95% confidence interval vertical bars) and predicted (open square symbols are the means with the 95% confidence interval bands as dashed lines) biomasses of R-1 (adult male crabs \geq 95 mm carapace width of carapace condition 1 and 2) snow crab in the year of the survey, 1997 to 2017. The predicted abundances are based on a relationship to the estimated abundances of R-2 (adolescent male crabs larger than 83 mm CW) in the previous year. Prediction of R-1 biomass for 2018 is based on abundances of R-2 estimated in 2017 as shown in Figure 11.

Figure 11. Estimated abundances (in millions; means and 95% confidence intervals) of R-4 (upper panel), R-3 (middle panel) and R-2 (lower panel) adolescent male crabs in the southern Gulf of St. Lawrence for the survey years 1997 to 2017.

The index of abundance of small male crabs (34-44 mm CW) from the trawl survey in 2017 remained at the same level to the index estimated in 2016 (Figure 12).

Figure 12. Index of abundance (in millions; means with 95% confidence intervals) of small male crabs of 34 to 44 mm CW, based on the trawl surveys conducted in the southern Gulf of St. Lawrence, 1997 to 2017.

Reproduction

The abundance of mature females is showing an increasing trend since the low value observed in 2006 (Figure 13). The increase of pubescent females observed in the 2017 survey suggests that the abundance of mature females may increase in the coming years (Figure 13).

Figure 13. Estimated abundances (in millions; means and 95% confidence intervals) of mature female (black circle symbols) and pubescent females (open square symbols) in the southern Gulf of St. Lawrence based on the trawl surveys from 1997 to 2017.

Environmental Considerations

In September 2017, near-bottom temperatures were near the mean value of the period 1981 to 2010 in most of the central portion of Area 12 as well as in Area 19. However, the bottom waters in Area 12E. Area 12F and the northwestern portion of the southern Gulf of St. Lawrence (channels connecting the slope of the Laurentian Channel to the Magdalen Shallows) were warmer than normal. Bottom waters in the western part of Chaleur Bay also were warmer than average. There was a band of cooler-than-normal bottom waters in the southwestern part of Area 12 that was stretching down from Miscou Island to both the west and east entrances of Northumberland Strait including St. George's Bay. Most of the snow crab fishing grounds had similar temperatures in 2017 compared to 2016 except for the area around PEI, the mouth of Chaleur Bay and in Area 19 where cooler bottom waters were present. The head of Chaleur Bay and a small area south of Shediac Valley had bottom waters that were significantly warmer in 2017 than in 2016. The snow crab habitat index (bottom area with temperatures from -1 to 3°C) was above the 1981-2010 average (4% above) in 2017 and increased by 5% from 2016 and 10% from 2015 (Figure 14). In 2017, the mean temperature (0.9°C) within the defined snow crab habitat area index (-1 to 3°C) decreased by about 0.1°C compared to 2016 (1.0°C), (Figure 14). The mean temperature was at the highest of the 45 year time series in 2012, decreased in 2013 and 2014, and remained slightly above the normal since then.

Snow crab is a stenothermic species with a preference for colder water temperatures. A temperature regime shift from cold to warm may have impacts on population dynamics of snow crab such as shortened reproductive cycles, increased per capita fecundity, and increased size at maturity, greater natural mortality, spatial contraction of habitat, and skewed sex ratio for reproduction. The outcome of climate change on snow crab population dynamics can be relatively abrupt and even detrimental, and the direction of the effect may be difficult to predict (Sainte-Marie et al. 2008).

Figure 14. Snow crab temperature habitat area index (km^2) that encompasses water temperatures of -1 to 3 °C (upper panel) and the mean temperature (°C) within the temperature area index (lower panel) in the southern Gulf of St. Lawrence, 1971 to 2017.

Sources of Uncertainty

There have been changes in snow crab survey vessel over the 1997 to 2017 assessment period, including a change in vessel in 2013 from the vessel which had been used during 2003 to 2012. There have never been any comparative experiments to assess if there were changes

in catchability between vessels. Changes in survey catch rates over time may not accurately reflect changes in stock size if survey vessels have different catchabilities.

The unstandardized catch per unit effort from the fishery is weakly correlated with the estimated biomass from the assessment. This results in differences in perception of stock abundance from the fishing industry observations (catch per unit of effort variations within the season and between years) from those of the assessment. A spatially and temporally designed analysis of the CPUE data and densities of crab from the survey is ongoing.

The distribution of snow crab within the southern Gulf of St. Lawrence and the proportions of the estimated abundance of commercial sized adult male crabs in each of the management areas show high inter-annual variations. The factors determining these relative distributions are not known but are seemingly related to movements of crab and recruitment pulses within the southern Gulf and in the eastern boundary area of the southern Gulf, rather than survival or exploitation. Changes in the environment, particularly the size of the Cold Intermediate Layer, are likely important factors but the influence of these factors on the movements and recruitment dynamics of crab are presently not known.

The estimated recruitment from the 2017 survey was within the confidence interval ranges compared to the values predicted from the R-2 in 2016. The situation is different than the 2016 value which was much higher and outside the confidence interval ranges compared to the value predicted from the abundance of R-2 in 2015. Predicting recruitment is uncertain because of a number of factors including variations in mortality, growth among stages and the variation in the proportion of pre-recruits that molt in any given year. In 2015, there was a high abundance and proportion of skip molters (crab that had not molted over the year) in the R-2 stage compared to previous years and it appears that this high abundance of skip molters resulted in a much higher molting rate and/or survival rate to the recruitment stage. The high incidence of skip molters in the R-2 stage was not observed in 2016 and 2017. Research on the factors that lead to skip molting in snow crab, either through density dependence (competition for resources) or annual variations in food availability, for example, should be undertaken.

Water temperatures in the southern Gulf vary annually. These changes in temperature can affect a number of life history processes including molting and growth, reproduction, and larval development. The impacts of changing conditions on the snow crab stock are uncertain but this warrants further study.

CONCLUSIONS AND ADVICE

The trajectory of stock abundance (biomass of commercial-sized adult male crabs as estimated from the trawl survey in the year before the fishery) versus exploitation rate in the fishery year for snow crab from the southern Gulf of St. Lawrence is shown in Figure 15. The commercial

biomass has varied between 30,920 t and 103,429 t during 1998 to 2017. Over this same period, exploitation rates have varied between 20.8% and 45.0%. The estimated biomass from the 2017 snow crab survey, which would be available to the fishery in 2018, is 66,021 t (95% CI 57,456 – 75,495 t). The 2017 survey biomass estimate is in the healthy zone.

Harvest decision rules that conform to the PA have been developed (DFO 2014b). These PA compliant harvest decision rules include rules for which the exploitation rate exceeds F_{lim} when the stock is in the healthy zone (DFO 2014b). The Snow Crab Advisory Committee agreed on the proportional harvest decision rule (variant 4 in DFO 2014b, Figure 16) to derive the exploitation rate and the TAC based on the estimated biomass from the southern Gulf of St. Lawrence snow crab survey. This decision rule and the corresponding estimated commercial biomass from the 2017 survey of 66,021 t, results in a selected exploitation rate of 38.3% and corresponding to a TAC of 25,286 t for the 2018 fishery (Figure 16).

A risk analysis was developed for the decision rule TAC and relative to other catch levels in 2018 (Table 8). The risk analysis indicates that the TAC derived from the harvest decision rule will result in a near zero chance of the residual biomass after the fishery being less than B_{lim} and a near 100% chance of the biomass for the next year's fishery being above B_{USR} and in the healthy zone of the PA (Table 8). The risk analysis also provides predictions of the commercial biomass in the 2018 survey, assuming the corresponding catch level is taken in 2018. At the decision rule TAC value of 25,286 t for the 2018 fishery, the commercial biomass predicted for the 2018 post-fishery survey and for the 2019 fishery, is 69,780 t, with a 95% confidence interval range of 55,110 to 84,030 t, an increase compared to the 2017 survey estimates, and in the healthy zone of the PA framework.

Figure 15. Trajectory of stock abundance (biomass of commercial-sized adult male crabs as estimated from the trawl survey in the year before the fishery) versus exploitation rate in the fishery year for snow crab from the southern Gulf of St. Lawrence. Year of the fishery is labeled on the figure. Error bars are 95% confidence intervals. Circle symbols are biomass and exploitation rate levels used to define the reference points. The squares are the years when the reference points were used within the PA to decide on the fishery quota. The biomass estimate available for the 2018 fishery (with 95% confidence interval) is also shown.

Figure 16. Harvest decision rule (solid black line; proportional variant 4; DFO 2014b) for the southern Gulf of St. Lawrence snow crab fishery and corresponding exploitation rate (0.383) for the 2018 fishery resulting from the commercial biomass estimate of 66,021 t (dashed-dotted line).

Table 8. Risk analysis of catch options in 2018 for the southern Gulf of St. Lawrence snow crab fishery showing probabilities of the hard-shell commercial-sized adult male remaining biomass falling below B_{lim} , and of the total commercial-sized adult male biomass being equal to or above B_{USR} post-fishery in 2018. The catch level of 25,286 t based on the agreed harvest decision rule is highlighted in the table. Also shown is the predicted (mean; 95% confidence interval range) commercial biomass from the 2018 survey assuming each corresponding catch level is fished.
