## Foreword

This series documents the scientific basis for the evaluation of aquatic resources and ecosystems in Canada. As such, it addresses the issues of the day in the time frames required and the documents it contains are not intended as definitive statements on the subjects addressed but rather as progress reports on ongoing investigations.

#### Abstract

Accurate estimates of mortality are critical in order to determine the abundance of any population. Mortality of Northwest Atlantic Harp Seals (Pagophilus groenlandicus) can be divided into 'unidentified' (or unreported) mortality which is estimated by a population model: ice-related mortality and human-induced mortality. The latter mortality consists of subsistence hunts in Greenland and the Canadian Arctic, a commercial hunt in Atlantic Canadian waters, as well as seals that are killed but not landed or reported during hunting ('struck and lost') and bycatch in commercial fishing gear. Commercial and subsistence hunts account for the majority of the removals.

The level of Canadian commercial catches have varied considerably with catches averaging approximately 288,000 Harp Seals annually prior to the introduction of quotas in 1972. Between 1972 and the demise of the large vessel hunt in 1982, an average of 166,000 seals were taken annually. Catches decreased after 1982 and remained low, averaging approximately 52,000 per year until 1995, at which time interest in the hunt increased significantly. Annual catches consisting primarily of young of the year (YOY) increased to an average of 272,600 between 1996 and 2006. Since then catches have declined, averaging 63,000 per year between 2009 and 2019. Since 1980 Greenland catches increased relatively steadily to a peak of approximately 100,000 in 2000. Between 2011 and 2017, catches have declined with an average of 60,000 seals reported annually.

Catches in the Canadian Arctic are not well documented but appear to be low with likely fewer than 1,000 Harp Seals taken annually in recent years. Estimates of Harp Seal bycatch in the Newfoundland Lumpfish (Cyclopterus lumpus) fishery increased from less than 1,000 per year in the early 1970 s to a peak of 46,400 in 1994, declining to approximately 5,000 by 2003 . Based on published bycatch rates in the Newfoundland Lumpfish fishery and data on Lumpfish landings, bycatch appeared to have increased again in the mid 2000s to approximately 35,000. Since then, Lumpfish landings have declined significantly and the bycatch of Harp Seals was estimated to be 555 in 2018.

Low numbers of Harp Seals are also caught in United States (U.S.) fisheries. Combining these various sources of human induced mortality results in estimates of total removals. Between 1952 and 1982, approximately 395,000 Harp Seals were killed annually. This declined to 177,000 per year between 1983 and 1995. With the renewed interested in hunting in Canada and increased catches in Greenland, the average annual removal from 1996-2006 was 476,000. Since 2008, reduced catches, particularly in Canada has lowered the annual total removals to approximately 200,000 Harp Seals per year. The greatest uncertainty in these estimates are associated with the bycatch in Newfoundland fisheries, the Greenland catch as well as struck and lost rates, although changes in the latter are unlikely to affect the abundance estimates significantly.

## INTRODUCTION

In order to estimate the abundance of any population, it is critical that the information available on the level of mortality is accurate. For many seal species, abundance is estimated using a population model that incorporates estimates of reproductive rates, pup production and mortality. In the case of the Northwest Atlantic Harp Seal (Pagophilus groenlandicus), mortality consists of identified human induced mortality, estimated environmentally mediate (ice) mortality of young of the year (YOY) and unidentified mortality (often referred to as 'natural' mortality, (M) which is estimated by the model (e.g., Hammill et al. 2015). The sources of mortality directly due to humans that have been identified are the commercial and personal use seal hunt in Atlantic Canada (referred to as 'Front' and 'Gulf'), the subsistence/commercial harvests in Greenland and the Canadian Arctic, animals that are killed but not landed during commercial or subsistence hunts and therefore are not accounted for in the catch statistics (referred to as 'struck and lost'), and incidental catches in commercial fishing gear (i.e., bycatch). Data on the levels of various components of this mortality have been compiled previously (e.g., Stenson et al. 1996, Lavigne 1999, Stenson et al. 2000, Walsh et al. 2000, Sjare and Stenson 2002, Stenson 2009) and summarized up to 2013 by Stenson (2014).

The objective of this study is to update available estimates of Canadian and Greenland catches, bycatch, and struck and lost to produce an estimate of human-induced removals for Northwest Atlantic Harp Seals up to 2019. These data will be used as input into a population model to assess the current abundance of Northwest Atlantic Harp Seals.

## DATA AND DISCUSSION

## COMMERCIAL AND SUBSISTENCE CATCHES

## Canadian Catches

Northwest Atlantic Harp Seals are taken in the commercial hunt in Canadian Atlantic waters off southern Labrador and/or the northeast coast of Newfoundland ('the Front', Northwest Atlantic Fisheries Organization [NAFO] Divisions 2J and 3KL), in the southern Gulf of St. Lawrence ('the Gulf', NAFO Division 4T) and in the northern Gulf of St. Lawrence (NAFO Division 4RS).
Although Harp Seals have been harvested commercially in Atlantic Canada since the 1700s, the highest level of catches occurred in the early to mid-1800s with an average of over 470,000 seal skins exported annually from Newfoundland between 1840 and 1850 (Ryan 1994, Hammill et al. 2011). Following this period, catches declined significantly to a low of 15,300 per year during World War II (Fig. 1).

Prior to the imposition of quotas in 1972 (Table 2), catches at the Front and in the Gulf were highly variable, ranging from 188,000-389,000 annually (average 288,000; SD=52,700; Table 1, Fig. 2). Between 1972 and 1982, the varying total allowable catch (TAC) (ICES 2019) resulted in an average annual catch of 166,000 (SD=21,300; range 124,000-202,000). From 1983 through 1995, annual catches were reduced (average 52,000; SD=21,300; range 19,000$94,000)$. In 1996 however, catches increased significantly $(243,000)$ and, with the exception of 2000, continued to increase, reaching a maximum of almost 366,000 in 2004. From 2003-2005, the TAC for Harp Seals in the Canadian commercial hunt was based upon a management plan that allowed for a total of 975,000 seals over three years with a maximum of 350,000 in any one year. Since then, TACs have been set annually to ensure that the population did not decline below the precautionary reference level (i.e., $\mathrm{N}_{70}$ or $70 \%$ of the maximum population size) within a 15 year period (Hammill and Stenson 2007). Between 1996 and 2006, an average of 272,671 ( $\mathrm{SD}=73,016$ ) seals were taken annually.

Catches have steadily declined since 2006 when a catch of 354,867 Harp Seals were reported (Table 1, Fig. 2). However, the statistics for this year assumed that 2,000 seals were taken in the Canadian Arctic which was double the level assumed to occur by Stenson (2014). In subsequent years, Arctic catches were not included in the reported estimates. Catches were significantly reduced in 2007 ( $224,745,83 \%$ of TAC) due to ice conditions, while low prices and ice conditions resulted in lower catches in 2008 with only $79 \%(217,850)$ of the TAC taken. Since 2009 Harp Seal catches have remained below 100,000 annually, averaging ~63,000 animals per year (Table 1). Catches declined to 35,382 ( $8 \%$ of the TAC) in 2015 after which they increased to 68,380 (17\% TAC) in 2016 and 81,742 (20.5\% TAC) in 2017. Catches declined again in the most recent years with 61,022 (15.25\% TAC) seals reported taken in 2018 and a preliminary estimate of 32,038 (8\% TAC) in 2019.

The catch statistics provided by International Commission for the Northwest Atlantic (ICNAF), NAFO, and Fisheries and Oceans Canada (DFO) Statistical Branch are reported according to pelage type. Based upon these reports, Front and Gulf catches can be split into YOY (age class 0 ) and seals one year of age and greater ( $1+$; see Table 1). For most years, the numbers of YOY seals taken annually were obtained directly from these data.

In 1998 and 1999 a portion of the catch was not identified according to pelage. The age of 7\% of the catch was not identified in 1998 so it was assumed that the proportion of YOY in this catch was the same as for the remainder of the catch for which ages were available. In 1999, approximately $22 \%$ of the catch did not have assigned ages. As these animals were all from the Gulf of St. Lawrence, the age structure of seals taken by the small boats in the Gulf (which were reported by age) was used. YOY accounted for $98 \%$ of these seals which was consistent with reports from the area. Since 2016, catches were listed as unspecified until the sales slips were compared and age class identified. In each of the subsequent years, a small proportion of the catches were not specified. These seals were assigned to an age class based upon the reported age classes for catches in the same area and month.
During the 1950s and early 1960s the proportion of YOY in the catch ranged from 47\% to 89\%, per year although in most years YOY made up 60-80\% of the catch (Table 1). From 1963-83 YOY accounted for over $78 \%$ of the catch in practically every year. The majority of these young were whitecoats taken during the large vessel hunt on the whelping concentrations. The proportion of YOY in the annual catch remained relatively high ( $70-80 \%$ ) during the mid to late 80s but was reduced to $40-60 \%$ per year during the first half of the 1990s (Table 1, Fig. 3). Since the late 1990s, over $97 \%$ of the annual catch has been YOY with beaters accounting for $100 \%$ of the harvest in some years. Since 2016, however, the proportion of seals one year and older (1+) in the catch has increased with the proportion of YOY in the catch averaging $90 \%$ annually.

## Greenland Catches

The Joint International Council for the Exploration of the Sea (ICES)/NAFO Working Group on Harp and Hooded Seals (WGHARP) examined the issue of stock identity of the Greenland harvest and concluded that all catches from west Greenland, and half of the catch from southeast Greenland should be considered to have come from the Northwest Atlantic Harp Seal stock (e.g., ICES 2008). Greenland catches for the years 1952 and 1953 were taken from Bowen (1982) and for 1954-2017 from ICES (2019). No data are available between 1988-92 and, following Stenson (2014), catches were estimated by linear interpolation between the available data.
Prior to 1975 reported catches of Northwest Atlantic Harp Seals varied from 4,000-19,000 (average 10,000; SD=4,000) per year with generally slightly higher catches in the 1950s than in
the 1960s and early 1970s (Table 3, Fig. 3). From the mid 1970s up to 1996, catches increased relatively consistently from approximately 7,000 in 1975 to approximately 100,000 in 2000. In the following decade, annual catches declined, averaging approximately 80,000 seals from 2001-2010 and approximately 60,000 between 2011 and the latest reports in 2017. In order to estimate total removals in 2018 and 2019, we assumed the average catch of the previous five years $(58,614)$. Since 2008, the number of Harp Seals caught in Greenland have been at a similar level to Canadian catches over the same time period.

## Canadian Arctic

Ringed Seals are the primary species of seals caught in the Canadian Arctic and there is very little information on the level of Harp Seal catches in the area. Information on historical catches in Nunavut were described by Stenson (2009) and there are no new data available. There are no estimates of catches in northern Quebec but the numbers are thought to be extremely small (M. Hammill, DFO, Quebec Region, pers. com.). As in Stenson (2009, 2014), we assumed that subsistence catches in the Canadian Arctic have remained at approximately 1,000 seals per year (Table 3, Fig. 3).

## BYCATCH

Harp Seals are caught in commercial fishing gear, particularly bottom set gillnets, in many parts of their range (Woodley and Lavigne 1991, Lien et al. 1994, Read 1994). A phone survey of fishermen to determine the level of bycatch of marine mammals indicated that while the occasional seal was caught in fishing gear, the primary source of mortality in Atlantic Canada is the spring Newfoundland Lumpfish (Cyclopterus lumpus) fishery which began in 1968 (Stenson unpublished data). This is likely due to the timing of the fishery with respect to the annual migratory pattern of Harp Seals and the large size ( $10.5 \mathrm{inch} / 26.7 \mathrm{~cm}$ ) of mesh used for Lumpfish.

Sjare et al. (2005) provided estimates of Harp Seal bycatch in the Newfoundland Lumpfish fisheries from 1970-2003. These estimates were based upon reported landings of Lumpfish roe as a measure of fishing effort and estimates of seal bycatch rates obtained from a bycatch logbook monitoring programme that was carried out by the DFO, Marine Mammal Section, from 1989 to 2003. The data were split into three areas; Northeast Coast (NAFO areas 3K and 3L except 3Lq), South Coast (NAFO areas 3Pn, 3Ps and 3Lq) and the West Coast (NAFO area $4 R$ ). Harp Seal bycatch per tonne of Lumpfish roe was calculated for each area based on the logbook data on the weight of Lumpfish roe landed and the number of seals caught per trip. These estimates were used to hind-cast from 1988 to 1970 based on Lumpfish roe landings over that time period and the average number of seals taken per tonne of roe from 1989 to 1991.

In previous assessments (e.g., Stenson 2014; Hammill et al. 2015), we incorporated these estimates up to 2003 and then applied an average of the last five years $(12,290)$ to the period 2004 onward. Since 2003 there have been significant changes in the Lumpfish fishery, therefore, we felt it necessary to revisit the estimates.
In the absence of new logbook data on catch rates, we used the bycatch rates estimated by Sjare et al. (2005; Table 4) and updated Lumpfish roe landing spanning 1970 through 2018 (Table 5). As in Sjare et al. (2005) we used the average of the bycatch rates from 1989 to 1991 from each area to hind-cast the 1970-1988 period. We then used the average rates of Harp Seal bycatch from 1999 to 2003 (i.e., the last five years) for the subsequent years. This assumes that the rate (i.e., number of seals caught per tonne of roe) has remained the same and that changes in fishing effort are reflected by changes in roe landings. An examination of
the landings per trip data, obtained from DFO Statistics Branch, from 1998-2018 indicated that the landings per fishing trip varied among years but no trend was observed.

Sjare et al. (2005) estimated the proportion of YOY seals caught from 1989 to 2000 using age class records provided by fishers over that time period. As in the Sjare et al. (2005), the average age classes from 1989 to 1991 were applied to the 1970-1988 period while averages for 1996 to 2000 were applied to 2000 onward (Table 6).

Bycatch was low until the early 1990s due to limited effort in the fishery (Table 7, Fig. 4). However, in the mid-1990s effort increased dramatically and catches rose to over 45,000 seals in 1994. By the late 1990s, bycatch dropped dramatically. However, it rose again briefly before dropping aging in the early 2000s. Another peak ( $\sim 35,000$ ) in bycatch occurred in the mid-2000s before declining. Since 2010, bycatch has remained low. In 2018 it was estimated to be 555 seals.

In addition to estimated bycatch in the Newfoundland Lumpfish fishery, we also included estimates of bycatch in the northeast U.S. fisheries (Waring et al. 2006, 2011, 2013; Hayes et al. 2019). Catch data since 1994 were obtained by independent fisheries observers in the Northeast Multispecies Sink Gillnet, Mid-Atlantic Coastal Gillnet and North Atlantic Bottom Trawl fisheries. The majority of catches observed were in the sink gillnet fishery while only occasional catches occurred in other fisheries. Generally, with the exception of few years, only small numbers of Harp Seals were caught in U.S. fisheries (Table 8). Catches in 2017-2019 were assumed to be equal to the average catches for the previous five years ( 57 seals). The proportion of young seals in the U.S. catches was assumed to be the same as that observed in the Newfoundland Lumpfish fishery.

## STRUCK AND LOST

During any hunt, some animals may be killed and either not recovered or reported. (i.e., 'Struck and Lost' [S\&L]). The level of S\&L will vary with the hunting method, skill of the hunter, location (e.g., on ice or in the water), weather conditions, age and condition of the seal, and the time of year, which is correlated with the thickness of the blubber layer in seals that lay down seasonal energy reserves (Sergeant 1991, Lavigne 1999, NAMMCO 2006). Lavigne (1999) reviewed available data on loss rates in older seals while Rowsell (1977) provided some data on loss rates for young Harp Seals (beaters) taken on the ice. Sjare and Stenson (2002) estimated S\&L rates in the Canadian commercial Harp Seal hunt between 1998 and 1999. DFO (1999) recommended that S\&L should be specifically identified as a removal for the purposes of assessing the population, even though it is unlikely to significantly impact the population estimates per se. This is because changes in the 'natural' morality estimated by the model will be adjusted to account for differences in S\&L levels.
Following the recommendations of DFO (2000) and following Stenson (2014), we assumed that recovery (and reporting) rates were $99 \%$ for YOY seals killed in southern Canadian waters prior to the end of the large vessel hunt in 1982 and $95 \%$ for YOY after this whitecoat hunt ended. The recovery rate for $1+$ seals taken in southern Canadian waters and all seals taken in Greenland or the Canadian Arctic was assumed to be $50 \%$ (Table 9).

## TOTAL REMOVALS

The total level of human induced mortality of Northwest Atlantic Harp Seals was determined by combining the estimates of reported Canadian and Greenland catches, S\&L, and incidental catches in commercial fisheries (Table 10, Fig. 5). Until the past decade, removals of Northwest Atlantic Harp Seals were driven primarily by catches in Canada. Between 1952 and the imposition of Canadian quotas in 1971, total removals averaged 395,000 seals per year. With
restrictions on catches in Canada, catch levels declined to an annual average of 230,000 for the 1972-1982 period. The end of the large vessel hunt in 1982 reduced the importance of the Canadian hunt while the Greenland component, particularly when S\&L is considered, increased (1983-1995, average=177,000 per year). Increased catches in all areas significantly increased the total removals between 1996 and 2008, with an annual average removal of 476,000 seals. Since 2008, reduced Canadian catches have lowered total removals again to an average of 200,000 Harp Seals per year, of which approximately $40 \%$ are YOY.

These estimates of removals may be impacted by a number of factors, particularly uncertainty in the estimated bycatch in the Newfoundland Lumpfish and other fisheries, the reported catch in the Greenland catch, and struck and lost rates in the Arctic and Greenland hunts. Given the number of seals taken in Greenland and the unknown age structure of this catch, errors can have a significant impact. Ugarte and Jakobsen (2006) presented preliminary data that suggested that our assumed level of S\&L in the Greenland hunt may be an overestimate. However, final estimates of Greenland S\&L are not available. Additional data on S\&L would allow us to improve these assumptions although changing S\&L is unlikely to change our understanding of the abundance significantly (Stenson et al. 1999). We have revised the estimated bycatch levels in the Newfoundland Lumpfish fishery downward due to significantly lower fishing effort in recent years. However, bycatch may also occur in other fisheries. Efforts are underway to estimate bycatch of Harp Seals in other Canadian fisheries but they appear to be only occasional as most of the fisheries occur after Harp Seals have migrated to their northern feeding grounds.

## ACKNOWLEDGEMENTS

We would like to thank A. Rosing-Asvid for the Greenland catch data and the late B. Sjare for estimates of Newfoundland bycatch rates.

${ }^{a}$ For the period 1946-1975 only 5-years averages are given.
${ }^{\mathrm{b}}$ All values prior to 1990 are from NAFO except where noted, recent data from DFO Statistics Branch.
${ }^{\text {c }}$ Landsmen values include catches by small vessels (<150 gr tons) and aircraft.
${ }^{\text {d }}$ NAFO values revised to include complete Quebec catch (Bowen, W.D. 1982).
${ }^{e}$ Large vessel catches represent research catches in Newfoundland and may differ from NAFO values.
${ }^{\mathrm{f}}$ Unspecified catches will be assigned to age class at a later date.
${ }^{9}$ Preliminary data.

Table 2. Major management measures implemented for Harp Seals in Canadian waters, 1961-2019.

| Year | Management Measure |
| :---: | :---: |
| 1961 | Opening and closing dates set for the Gulf of the St. Lawrence and Front areas. |
| 1964 | First licensing of sealing vessels and aircraft. Quota of 50,000 set for southern Gulf (effective 1965). |
| 1965 | Prohibition on killing adult seals in breeding or nursery areas. Introduction of licensing of sealers. Introduction of regulations defining killing methods. |
| 1966 | Amendments to licensing. Gulf quota areas extended. Rigid definition of killing methods. |
| 1971 | TAC for large vessels set at 200,000 and an allowance of 45,000 for landsmen. |
| 1972-1975 | TAC reduced to 150,000, including 120,000 for large vessel and 30,000 (unregulated) for landsmen. Large vessel hunt in the Gulf prohibited. |
| 1976 | TAC was reduced to 127,000. |
| 1977 | TAC increased to 170,000 for Canadian waters, including an allowance of 10,000 for northern native peoples and a quota of 63,000 for landsmen (includes various suballocations throughout the Gulf of St. Lawrence and northeastern Newfoundland). Adults limited to $5 \%$ of total large vessel catch. |
| 1978-1979 | TAC held at 170,000 for Canadian waters. An additional allowance of 10,000 for the northern native peoples (mainly Greenland). |
| 1980 | TAC remained at 170,000 for Canadian waters including an allowance of 1,800 for the Canadian Arctic. Greenland was allocated additional 10,000. |
| 1981 | TAC remained at 170,000 for Canadian waters including 1,800 for the Canadian Arctic. An additional allowance of 13,000 for Greenland. |
| 1982-1987 | TAC increased to 186,000 for Canadian waters including increased allowance to northern native people of 11,000. Greenland catch anticipated at 13,000. |
| 1987 | Change in Seal Management Policy to prohibit the commercial hunting of whitecoats and hunting from large ( $>65 \mathrm{ft}$ ) vessels (effective 1988). Changes implemented by a condition of licence. |
| 1992 | First Seal Management Plan implemented. |
| 1993 | Seal Protection Regulations updated and incorporated in the Marine Mammal Regulations. The commercial sale of whitecoats prohibited under the Regulations. Netting of seals south of $54^{\circ} \mathrm{N}$ prohibited. Other changes to define killing methods, control interference with the hunt and remove old restrictions. |
| 1995 | Personal sealing licences allowed. TAC remained at 186,000 including personal catches. Quota divided among Gulf, Front and unallocated reserve. |
| 1996 | TAC increased to 250,000 including allocations of 2,000 for personal use and 2,000 for Canadian Arctic. |
| 1997 | TAC increased to 275,000 for Canadian waters. |
| 2000 | Taking of whitecoats prohibited by condition of license |
| 2003 | Implementation of three year management plan allowing a total harvest of 975,000 over three years with a maximum of 350,000 in any one year. |
| 2005 | TAC reduced to 319,517 in final year of three year management plan |
| 2006 | TAC increased to 335,000 including a 325,000 commercial quota, 6,000 original initiative, and 2,000 allocation each for Personal Use and Arctic catches |
| 2007 | TAC reduced to 270,000 including 263,140 for commercial, 4,860 for Aboriginal, and 2,000 for Personal Use catches |
| 2008 | TAC increased to 275,000 including a 268,050 for commercial, 4,950 for Aboriginal and 2,000 for Personal Use catches. Implementation of requirement to bleed before skinning as a condition of licence. |
| 2009 | TAC increased to 280,000 based upon allocations given in 2008 plus an additional 5,000 for market development. Additional requirements related to humane killing methods were implemented. |
| 2010 | TAC increased to 330,000. |
| 2011 | TAC increased to 400,000. |
| 2017 | TAC no longer announced. Catches monitored. |

Table 3. Reported catches of Harp Seals in the northwest Atlantic for 1952-2019. Estimated catches are indicated by shading and symbol (*). The Greenland catches are made up of the Table 6 West Greenland catches and $1 / 2$ of the SE Greenland. The other half of the SE Greenland and the NE Greenland are assigned to the West Ice population.
