## Foreword

This series documents the scientific basis for the evaluation of aquatic resources and ecosystems in Canada. As such, it addresses the issues of the day in the time frames required and the documents it contains are not intended as definitive statements on the subjects addressed but rather as progress reports on ongoing investigations.

## ABSTRACT

The anadromous northern-form of Dolly Varden (*Salvelinus malma malma*) from the Rat River, Northwest Territories was assessed through a mark-recapture program between 2009 and 2014 which evaluated trend in abundance and biological characteristics to determine if the population was sustainably harvested. Seining was conducted annually in late-September at the spawning and overwintering location in Fish Creek to collect live-sampled biological data (length, sex, reproductive status, and growth) and periodically to apply tags. Recapture of tagged fish occurred the following year in either the subsistence fishery near the mouth of the Rat River or while seining in the headwaters (Fish Creek). The two recapture methods generated independent abundance estimates for 2009, 2010, and 2013. These estimates suggest the population has increased to ~ 12,000–15,000 fish from a low of 2,900 estimated in 2004 and were amongst the highest abundances observed since 1995 when the mark-recapture program was initiated. Biological information collected during seining between 2009 and 2014 revealed a wide range of sizes with an increase in the proportion of larger sizes in more recent years. Female spawners were mainly between 450 and 575 mm in length while male spawners tended to be larger and primarily distributed between 500 and 600 mm. Non-spawners were typically smaller in size compared to spawners. Males had higher annual growth compared to females and spawned in consecutive years less frequently (12.5%) than females (50.9%). The growth of females spawning in consecutive-years in 2009-2014 was higher compared to 1995–1996, yet was lower than during 2004-2005. Sampling conducted in the upper most reaches of Fish Creek detected a high proportion of anadromous spawners and a large number of both the resident life history (sexually mature non-anadromous) and pre-smolt juveniles, suggesting this recently examined location provides important spawning and rearing habitat. Data from the mark-recapture program suggest the population is currently stable and sustainably harvested.

---

## INTRODUCTION

The population of northern-form Dolly Varden (*Salvelinus malma malma*) from the Rat River is one of several known to originate from rivers located in the Richardson Mountains. The watershed of the Rat River is situated in both the Yukon Territory and Northwest Territories (688 km<sup>2</sup>) and is fed by many small and shallow high-gradient tributaries (Jessop et al. 1973). One of these, Fish Creek, the spawning tributary for the stock, has areas where ground water flows on a perennial basis into the creek which provides suitable locations for Dolly Varden to spawn and overwinter (Mochnacz et al. 2010). The water flows out of the ground at a constant temperature (~ 4°C), maintaining small areas of open water in some stretches of the creek during the winter that produce an aufeis field (layered ice) further downstream that is believed to delineate the lower extent of overwintering habitat (see Sandstrom et al. 2001). Given the importance of Fish Creek for spawning, it is also an important location for juvenile rearing and feeding.

Anadromous Dolly Varden from the Rat River are an important cultural and subsistence resource for both Gwich'in and Inuvialuit peoples mainly from communities in the Mackenzie Delta, in particular Aklavik and Fort McPherson, Northwest Territories (Figure 1). The Gwich'in have harvested Dolly Varden in the Mackenzie Delta and lower reaches of the Rat River during the upstream (return) migration for generations (Benson 2010). They have also traditionally harvested Dolly Varden from the pools of Fish Creek at the spawning and overwintering area (locally described as 'Fish Hole') by sweeping the pools (with a small-mesh gill net) and setting fish traps in early winter (Benson 2010). However, this area is currently closed to fishing activity except for scientific and educational purposes. Dolly Varden from the Rat River stock are also harvested by Inuvialuit in the Beaufort Sea as part of a mixed-stock fishery during summer, and by both Inuvialuit and Gwich'in in Aklavik during the upstream migration (Figure 1).

Gwich'in harvesters identified a decline in the abundance of the Rat River stock in the early 1980s (Benson 2010). In response, the Rat River Working Group was established in 1995 to provide advice to the co-management bodies responsible for the fisheries management in the Mackenzie Delta. A mark-recapture program was established in 1995 to periodically (on a three year basis) provide abundance estimates for the Rat River stock. A further drop in abundance observed in 2004 prompted the Rat River Working Group to establish a voluntary closure of the fishery for Dolly Varden in the Mackenzie Delta and Rat River between 2006 and 2008 (inclusive; Howland et al. 2012). The decline observed in the Rat River in addition to past declines in the Big Fish River stock was one of the reasons for listing the northern-form Dolly Varden in Canada as a species of 'Special Concern' by the Committee on the Status of Endangered Wildlife in Canada (COSEWIC) in 2010 (COSEWIC 2010). Concomitantly, an integrated fisheries management plan (IFMP) was signed among the Gwich'in Renewable Resources Board (GRRB), Fisheries Joint Management Committee (FJMC), Fisheries and Oceans Canada (DFO), and Parks Canada to guide the management of Dolly Varden in the western Arctic over the next five years (2010–2015; DFO 2010).

The Rat River stock was formally assessed in 2001 (Harwood 2001, DFO 2001 [data up to 2001]), and 2008 (Roux et al. 2012, DFO 2014 [data up to 2008 and 2007, respectively]) using the time series of data from the sampling programs, including annual harvest monitoring for the Rat River (see Harwood et al. 2009) and periodic population estimates from mark-recapture studies (see Sandstrom et al. 2009). The proper implementation of the IFMP and any future evaluation by COSEWIC requires an updated assessment.

Location of rivers and creeks\* in the Inuvialuit Settlement Region and Gwich'in Settlement Area (red lines delineate border) known to have anadromous Dolly Varden and locations along the Beaufort Sea coast where harvesting of Dolly Varden occur. Insert on lower left is a satellite image (Google Earth) of Fish Creek, the spawning and overwintering tributary of the Rat River stock, showing the location of the upper and lower reaches where seining was conducted (end of September). \*Joe Cr., Firth R., Babbage R., Big Fish R./ Little Fish R., Rat R./ Fish Cr., and Vittrekwa R.

## OBJECTIVES

Data collected from a mark-recapture study conducted between 2009 and 2014 were used to assess the population status of anadromous Dolly Varden from the Rat River, specifically to:

1. Calculate population abundance estimates for 2009, 2010, and 2013 based on two separate methods of recapture and compare to prior estimates;

2. Summarize biological characteristics of the population from live-sampling conducted in Fish Creek at spawning and overwintering locations in September (length, sex, maturity/ reproductive status, and growth) and compare to data collected in previous years.

## METHODS

### THE CAPTURE AND SAMPLING OF FISH AT THE SPAWNING AND OVERWINTERING AREA

Over the time frame considered in this assessment (2009–2015), seining was conducted at the spawning and overwintering area in Fish Creek at the end of September to collect fishery-independent biological information (live sampling) and attach t-bar tags to up to 500 Dolly Varden for a mark-recapture study to estimate population abundance (Appendix 1). The seine net and technique used to capture fish were consistent with previous work described by Sandstrom et al. (2009), where seining was conducted in pools located in the lower reach of Fish Creek (N 67.76582, W 136.30533) near the start of an aufeis field down to just above a rock slide area that is situated approximately three kilometers from its confluence with the Rat River (Figure 1). Seining has occurred periodically between 1995 and 2004 to collect biological data and tag fish for recapture in the following year by the Rat River Harvest Monitoring Program (Table 1). Since 2007, seining has occurred annually, however tagging only occurred in 2007, 2009, 2010, 2013, and 2014 for recapture the following year in both the Rat River Harvest Monitoring Program and the seining program (Table 1).

*Table 1. Location, dates, number of pools seined, and tagging status (Yes or No) for anadromous Dolly Varden from the Rat River captured in the spawning and overwintering areas in Fish Creek, a tributary to the Rat River.*

Location	Year	Dates	Number of Pools Seined	Fish Tagged
Lower reach	2014	Sept. 24, 27	10	Y
Lower reach	2013	Sept. 24 - 25	15	Y
Lower reach	2012	Sept. 26	12	N
Lower reach	2011	Sept. 24	8	N
Lower reach	2010	Sept. 21 - 22	10	Y
Lower reach	2009	Sept. 24, 27	8	Y
Lower reach	2008	Sept. 23	5	N
Lower reach	2007	Sept. 27 - 28	10	Y
Lower reach	2004	Sept. 20 - 22	14	Y
Lower reach	2001	Sept. 30 - Oct. 3	12	Y
Lower reach	1997	Sept. 21 - 26	12	Y
Lower reach	1995	Sept. 29 - 30, Oct. 2	11	Y
Upper reach	2014	Sept. 25	5	Y
Upper reach	2013	Sept. 27	3	Y

In addition to sampling conducted in the lower reach, seining was also conducted at the upper reach of Fish Creek (N 67.90375, W 136.51607) in 2013 and 2014 to characterize and tag Dolly Varden utilizing this area (Figure 1). This location was of interest due to observations of multiple reaches of open water above the aufeis area in this part of the creek, including a section downstream of Vunta Creek at the base of the White Mountains during a March 2009 habitat

---

survey (Mochnacz et al. 2010) (Figure 1). Further surveys in the upper reach of Fish Creek during March and early September 2013 observed small-size fish (presumably juveniles, species undetermined) and anadromous-sized Dolly Varden in spawning coloration, respectively (N. Mochnacz and K. Dunmall, DFO, pers. comm. and K. Maier, GRRB, pers. comm.), suggesting it may serve as an important spawning/rearing area. Biological data will be presented separately for the upper and lower reaches of Fish Creek.

Briefly, a seine net was used to sweep a series of pools in the river where fish were congregated. Each fish captured in the net was identified to species and measured for fork length ( $\pm 5$  mm). The life history type of each Dolly Varden was identified and, for anadromous fish, the reproductive status was recorded ('non-spawner' or 'spawner') along with the sex if it was in spawning condition. Non-spawners (also termed 'silvers') are either immature smolts or resting adults that are silver in colour. Each anadromous fish was examined for the presence of a tag near the base of the dorsal fin and, if present, the tag number and colour were recorded. If a Dolly Varden had no tag and was  $>300$  mm, it was tagged with an individually coded plastic t-bar tag at the base of the dorsal fin and then released back into the water.

## POPULATION ABUNDANCE

Population estimates for Dolly Varden from the Rat River in 2009, 2010, and 2013 were generated by tagging fish at the spawning and overwintering area and using two different methods of recapture in the following year (2010, 2011, and 2014, respectively). The first method of recapture was through the subsistence harvest monitoring program, described in Sandstrom et al. (2009), which is consistent with the methodology used in estimating abundance prior to 2007. The second method of recapture was seining at the spawning and overwintering area. Since 2007, it has been possible to generate two estimates of abundance using both methods of recapture. The model used to estimate population size was based on single-year census (Petersen model).

Mark-recapture model assumptions of no recruitment into the population and tag loss were not met in this case and corrections were made (see Sandstrom et al. 2009, Gallagher et al. 2011). Both recapture methods assume all tags were available (excluding fish that experience natural mortality) and that tagged and untagged individuals were randomly mixed by the following year. For the recaptures from the subsistence fishery, it was assumed that most if not all available tags were vulnerable for recapture given that monitoring was conducted over the majority of the migration period (approximately six weeks; end of July to early September). It was also assumed that the number of untagged fish captured in the subsistence fishery was accurately recorded, as trained harvest monitors were instructed to collect this information on field log sheets (Sandstrom et al. 2009). For recaptures obtained during the fall seining, contrary to recaptures from the fishery, it was assumed that the large majority of the population was distributed within a relatively small geographic area and that sampling could therefore be conducted over a short period of time (few days). The estimate generated from fall seining (carried out after the subsistence fishing period) assumed that all tags captured in the subsistence fishery had been reported.

The Chapman modification of the Petersen equation was used to estimate population size (N):

$$N = \frac{(M + 1)(C + 1)}{(R + 1)} - 1$$

---

where M= number of individuals marked, C= total number of individuals captured while trying to collect marked fish, and R= number of individuals marked that were recaptured. The uncertainty of N is determined by calculating the variance (Var):

$$Var = \frac{(M + 1)(C + 1)(M - R)(C - R)}{(R + 1)^2(R + 2)} - 1$$

Seber (1982, Appendix 1) recommends the Poisson distribution to calculate 95% confidence intervals (C.I.) if  $R/C < 0.1$  and  $R/M < 0.1$ , which applies in this study. To calculate the intervals, coefficients were determined based on the frequency of R, according to Seber (1982), and applied to the product of MC to determine the lower and upper limits. To control for the issue of recruitment of unmarked individuals into the component of the population being evaluated (i.e., due to growth between sample 1 and sample 2), the lower end of the size range was adjusted upwards using the established growth relationship observed from tag recaptures to exclude those fish in the recapture event that would have been too small for tagging in sample 1. To compare with prior population estimates from the Rat River (see Sandstrom et al. 2009, Roux et al. 2012), the 95% confidence intervals from past Petersen estimates were re-calculated using a Poisson distribution.

## **BIOLOGICAL INFORMATION**

For all analyses, non-spawners, and female and male spawners were examined separately. Differences in length among males and females in spawning condition and non-spawners captured in the seine net were evaluated with a Mann-Whitney U test due to the high number of instances of non-parametric distribution of  $\log_{10}$  transformed length data among years. Between 2009 and 2014, lengths of all non-spawners and female spawners were non-parametrically distributed (except in 2011), while male spawner lengths were always parametrically distributed. A Kruskal-Wallis test or analysis of variance (ANOVA) test was used to determine if length was similar among sampling years while between-years comparisons were made using Mann-Whitney or t-tests.

Annual growth was examined using length data from the recapture of tagged fish that were at large for 0.9 to one year, between 2010 and 2014, from the Rat River Harvest Monitoring Program and the seining program in Fish Creek. Data with discrepancies in the sex of the fish between capture and recapture ( $n = 3$ ) and where length was greater when tagged ( $n = 3$ ) were omitted. Annual growth was calculated by subtracting the length at recapture from the length at capture. Growth was plotted against length at capture and fitted with a linear regression. Length at capture was also plotted against length at recapture to illustrate the annual change in length of Dolly Varden. Analysis of covariance (ANCOVA) was used to test for differences in growth between sexes (all years combined and regardless of reproductive status from one year to the next) using length at initial capture as a covariate. Effects of change in annual reproductive status (i.e., skip spawner or consecutive-year spawner) on growth were examined only for female spawners as the sample size of males was too low. Annual growth of female consecutive-year spawners from 2009-2014 ( $n = 26$ ) was compared to earlier years (1995-1996  $n = 26$ , and 2004-2005  $n = 14$ ) to examine whether there had been a temporal change in growth characteristics; an approach consistent with Sandstrom et al. (2009).

Tagged Dolly Varden sampled for sex and maturity when recaptured in the following year either by harvest monitors (Shingle Point, Mackenzie Delta, or Rat River) or seining were used to tabulate the spawning frequency for both males and females (note: samples with discrepancies in length [length at capture > recapture] were included [ $n = 3$ ] assuming reproductive status was properly recorded upon recapture).

## RESULTS

### POPULATION ABUNDANCE

Abundance estimates between 2009 and 2013 varied between years and differed between recapture methods within a single year (Table 2, Figure 2). Estimates from harvest monitoring showed the population had increased steadily from 6,625 fish in 2009 up to 14,891 in 2013. The estimates from seining at Fish Creek indicated that abundance remained unchanged between 2009 and 2010 (~ 5,800 fish) and subsequently increased to approximately 10,000 fish by 2013. Variance around the estimates differed among years and increased with increasing abundance. However, the seine recapture estimates had lower overall variance than the harvest monitoring estimates (Figure 2). The proportion of the population that was tagged each fall ranged between approximately 4 and 8%. Compared to population estimates between 1995 and 2007, the abundance in 2013 was among the highest observed since the mark-recapture program was initiated (Figure 2).

*Table 2. Calculations of the Petersen model used to estimate the population abundance and 95% confidence intervals (C.I.) (Poisson distribution) of anadromous Dolly Varden from the Rat River in 2009, 2010, and 2013 based on the recapture of fish by the harvest monitoring program (subsistence gill nets) and seining at the spawning and overwintering area.*

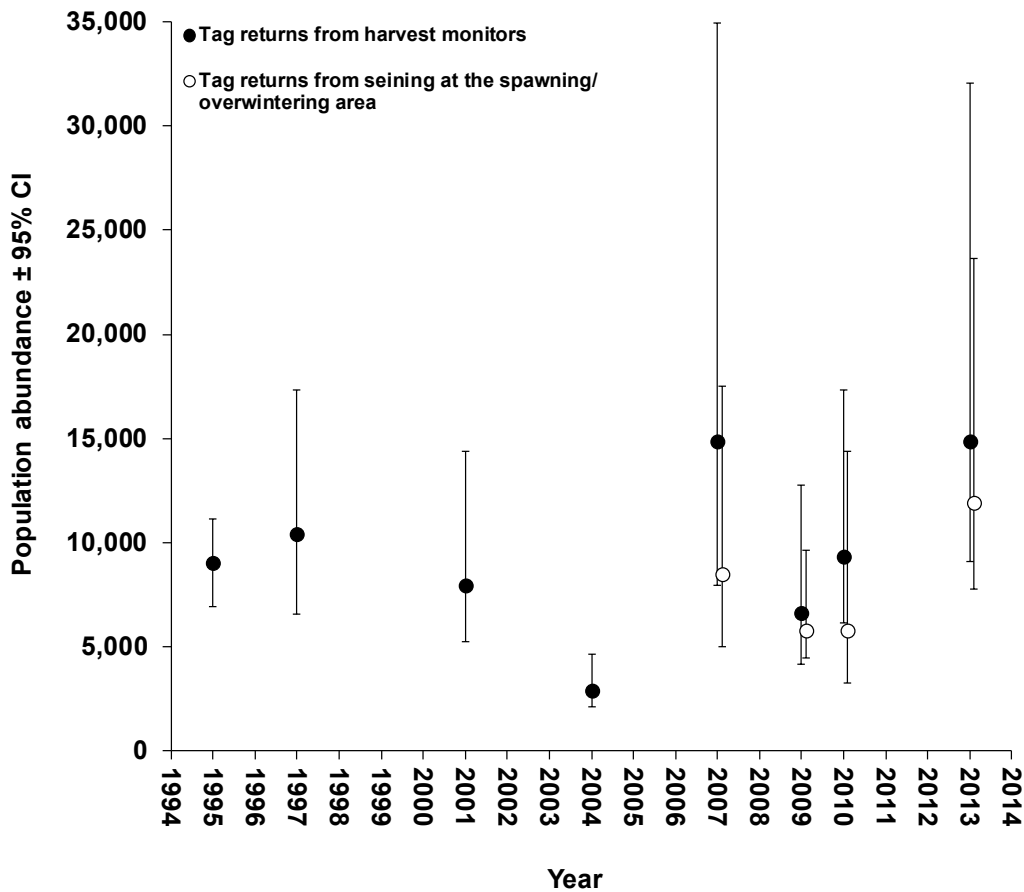

Figure 2. Population abundance estimates of anadromous Dolly Varden from the Rat River between 1995 and 2013.

## Length

The body size of the total sample of anadromous Dolly Varden sampled in the lower reach of Fish Creek between 2009 and 2014 ranged between 295 and 730 mm. Female spawners ranged between 370 and 685 mm with most distributed between 450 and 575 mm (Figure 3, 4). Compared to female spawners (range of means = 466-524 mm), male spawners (range of means = 486-624 mm) were significantly larger ( $U = 55093$ ,  $p < 0.001$ ) (Table 3). Although both females and males had similar minimum size-at-maturity (390 mm), male spawners were mainly distributed among larger sizes (500-600 mm) and also attained higher maximum length (up to 730 mm) (Figure 3, 4). Non-spawners were smaller in size compared to both female ( $U = 493598$ ,  $p < 0.001$ ) and male ( $U = 47967$ ,  $p < 0.001$ ) spawners (Table 3). Non-spawners ranged between 295 and 710 mm and were distributed mainly between 400 and 575 mm. The length frequency distribution of non-spawners had a bimodal pattern in most years with a high proportion of juveniles between 350 and 375 mm in 2012 and 2014 (Figure 3).

Between 2009 and 2014, significant inter-annual differences in length were detected for female ( $X^2 = 137$ ,  $d.f. = 5$ ,  $p < 0.001$ ) and male ( $F = 15.3$ ,  $d.f. = 5,223$ ,  $p < 0.000$ ) spawners, and non-spawners ( $X^2 = 161$ ,  $d.f. = 5$ ,  $p < 0.001$ ) (Appendix 2). In 2011 and 2012, the median length (~ 520 mm) and proportion of large-size female spawners was relatively high (Figure 4). A similar pattern was observed in male spawners with median values of 585 - 630 mm although

---

the range of sizes in 2011 was considerably truncated. Non-spawners were mostly distributed among adult sizes in 2010 and 2011 and became increasingly distributed between both juvenile and adult length classes from 2012 to 2014 (Figure 3).

The longer time-series of data available from past seining (Sandstrom et al. 2009) suggested that the size of female spawners has remained relatively stable since 1995, with median values demonstrating a slightly sinusoidal pattern over time (Table 3, Figure 3, 4). The length of male spawners had varied more over time with a high proportion of small sizes (< 500 mm) observed in 1995 and 1997 and a greater distribution among lengths > 500 mm thereafter (Table 3, Figure 3, 4). Non-spawners also demonstrated a slight sinusoidal pattern over time with greater sizes observed from 2010-2013. Bimodal length frequency distributions with a high proportion of fish between 325 and 375 mm were observed in 2007 and 2008 (Figure 3). Among recent sampling years (2010-2014), the proportion of large-size fish ( $\geq 550$  and  $\geq 600$  mm; female and male spawners and non-spawners combined) captured in the seine net had increased considerably compared to earlier years (Figure 5).

Anadromous Dolly Varden seined in the upper reach of Fish Creek in 2013 and 2014 were primarily male and female spawners that were similar in size to those captured in the lower reach (Table 3, Figure 6).

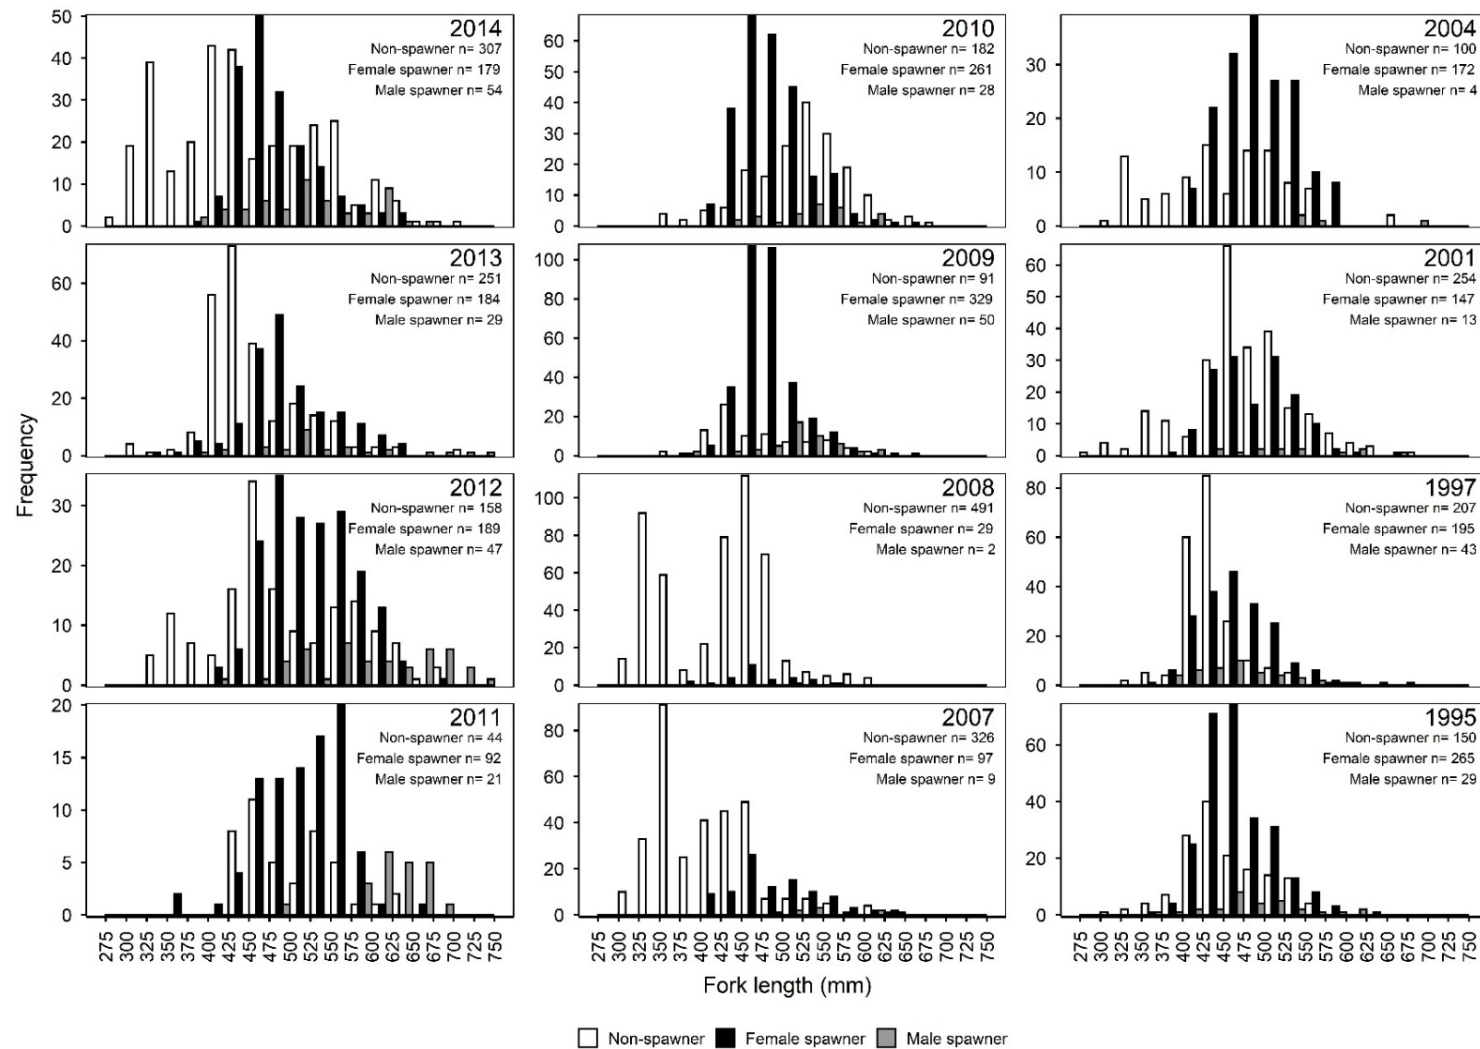

Figure 3<sup>1</sup>. Length frequency distribution of Dolly Varden from the Rat River captured by seine net at the spawning and overwintering area (lower reach) in Fish Creek between 1995 and 2014 and identified as non-spawner, female spawner, and male spawner. Note: in 2001 n = 3 non-spawners were < 250 mm.

<sup>1</sup> Erratum December 2021 – Figure corrected.

Table 3. Mean ( $\pm$  standard deviation), median, range, and sample size ( $n =$ ) of fork length (mm) of anadromous Dolly Varden from the Rat River identified as non-spawners, and female and male spawners captured in the lower (above dashed line) and upper reaches (below dashed line) of Fish Creek at spawning and overwintering locations captured using a seine net in late September to early October between 1995 and 2014\*.

\*Seining was conducted in 1981 and 1982 yet sample sizes were too low for meaningful comparison

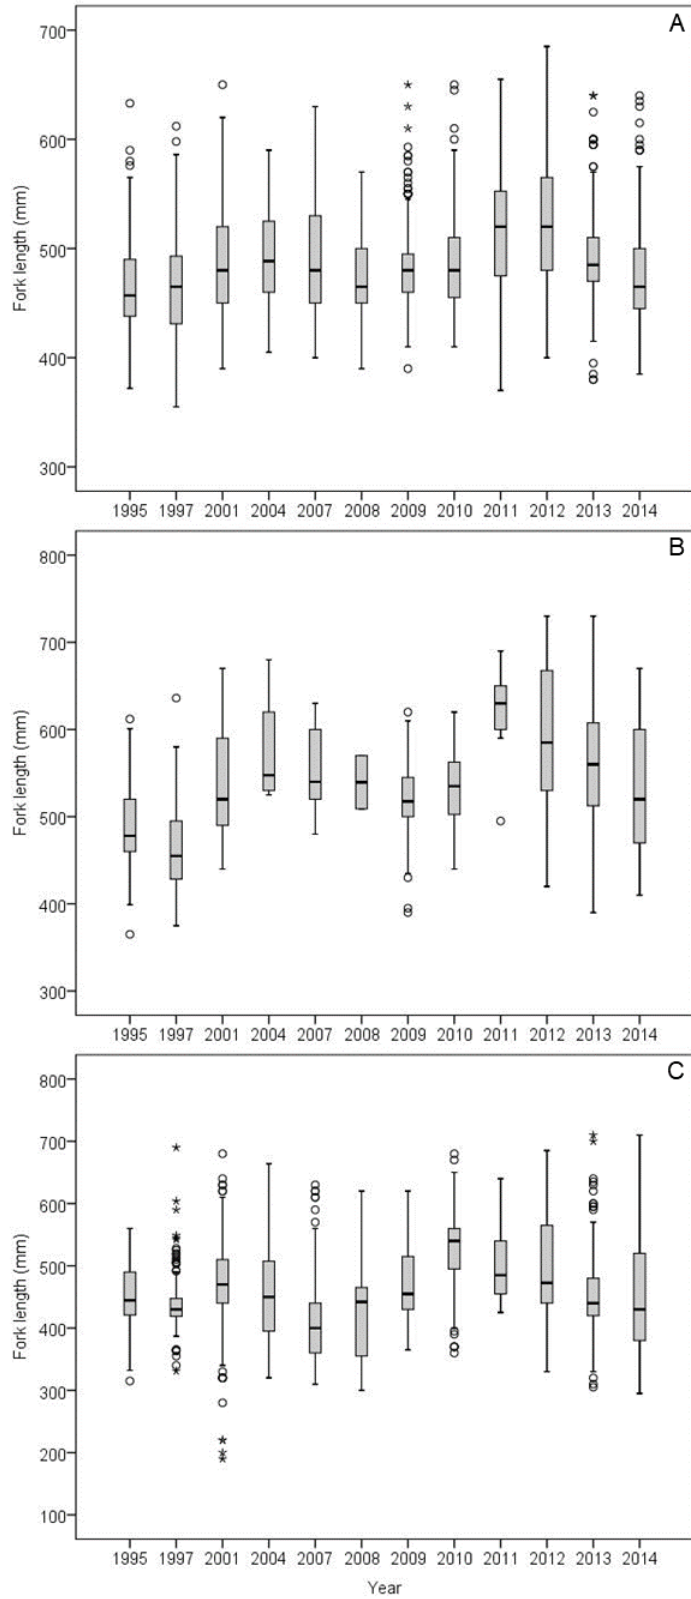

Figure 4. Box plot of length [median, quartiles and outliers ( $\circ$ ,  $\star$ )] of Dolly Varden from the Rat River captured by seine net at the spawning and overwintering area (lower reach) in Fish Creek between 1995 and 2014 and identified as A) female spawners, B) male spawners, and C) non-spawners.

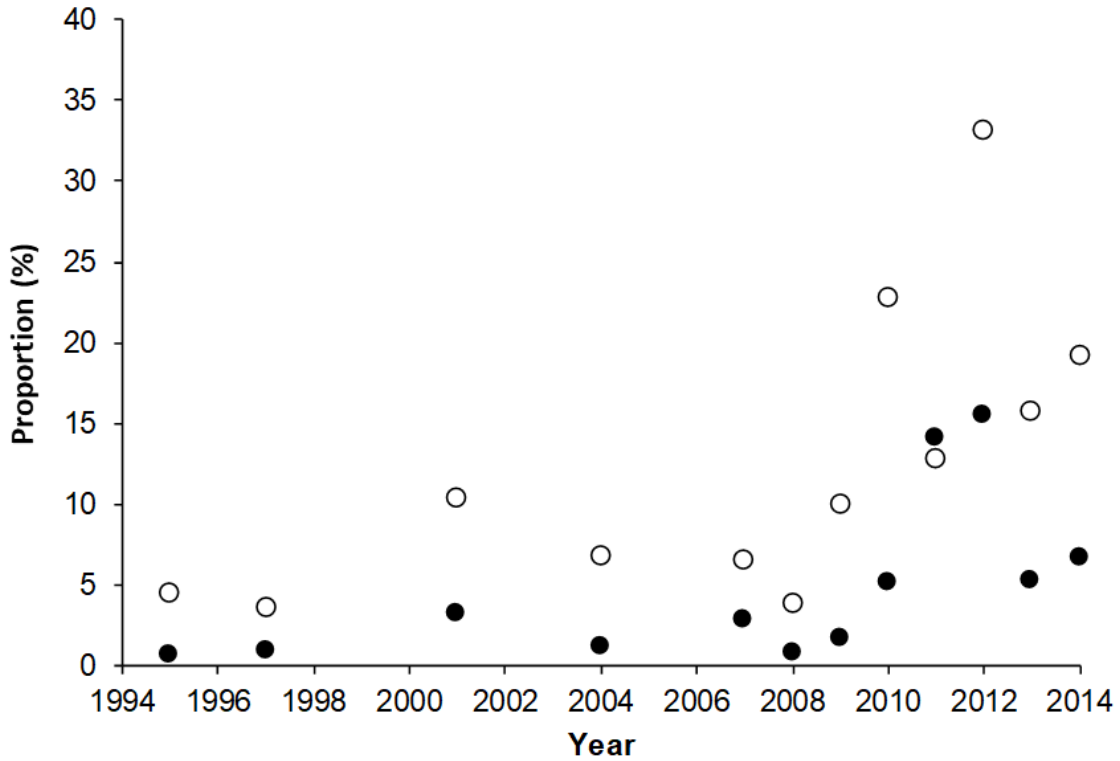

Figure 5. Proportion (%) of sizes  $\geq 550$  ( $\circ$ ) and  $\geq 600$  ( $\bullet$ ) mm of Dolly Varden (female and male spawners and non-spawners combined) from the Rat River captured by seine net in Fish Creek at the lower spawning and overwintering area between 1995 and 2014.

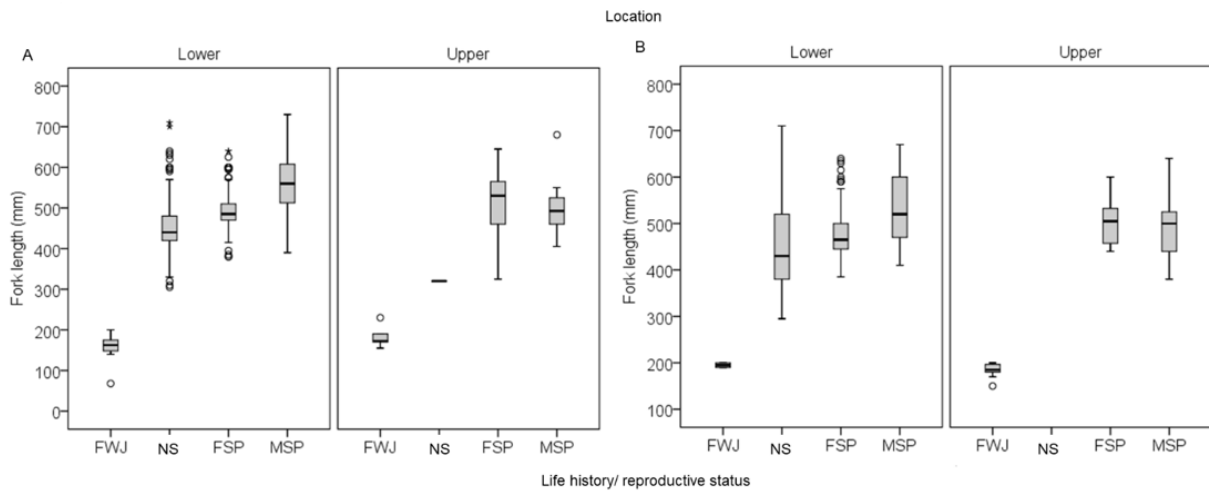

Figure 6. Box plot of length [median, quartiles and outliers ( $\circ$ ,  $\star$ )] of Dolly Varden from the Rat River captured by seine net in the lower and upper reaches of Fish Creek at spawning and overwintering locations in A) 2013 and B) 2014 and identified as freshwater juveniles (pre-smolt) (FWJ), non-spawners (NS), female spawners (FSP), and male spawners (MSP).

## Growth

The estimated annual growth of tagged Dolly Varden was based on 95 recapture events between 2010 and 2014 of fish at large between approximately 0.9 and one year. Of these, 58 were recaptured while seining (three were recaptured twice in separate years) and 37 recaptured in the Rat River Harvest Monitoring program. It should be noted that three recaptures were omitted because recapture length was less than capture length (Figure 7). The annual change in length from one year to the next was described with the linear equation:

$$\text{Length (mm)}_{\text{year } 2} = 0.2 \times \text{Length (mm)}_{\text{year } 1} + 147.7$$

Males ( $n = 19$ ) demonstrated a higher rate of growth compared to females ( $n = 71$ ), regardless of reproductive state from one year to the next (consecutive-year spawner and non-spawner, or an annual change from non-spawner to spawner and vice versa) (slope  $F = 5.7$ ; d.f. = 1, 87;  $p = 0.019$ ; intercept  $F = 30.8$ ; d.f. = 1, 87;  $p < 0.001$ ) (Figure 8). Female spawners that were recaptured as non-spawners ( $n = 26$ ) one year later demonstrated a significantly higher growth compared to consecutive-year spawners ( $n = 26$ ) (slope  $F = 19.8$ ; d.f. = 1, 49;  $p < 0.001$ ; intercept  $F = 9.1$ ; d.f. = 1, 49;  $p = 0.004$ ) (Figure 9). The rate of growth of males whose annual change in reproductive status was from spawner to non-spawner and vice versa were mainly distributed among lengths between 400 and 500 mm (Figure 10). Growth of females spawning in consecutive-years in 2009-2014 was significantly higher compared to 1995-1996 (slope  $F = 5.2$ ; d.f. = 1, 47;  $p = 0.027$ ; intercept  $F = 17.5$ ; d.f. = 1, 48;  $p < 0.000$ ) and lower than 2004-2005 (slope  $F = 2.0$ ; d.f. = 1, 36;  $p = 0.16$ ; intercept  $F = 6.9$ ; d.f. = 1, 36;  $p < 0.012$ ) (Figure 11).

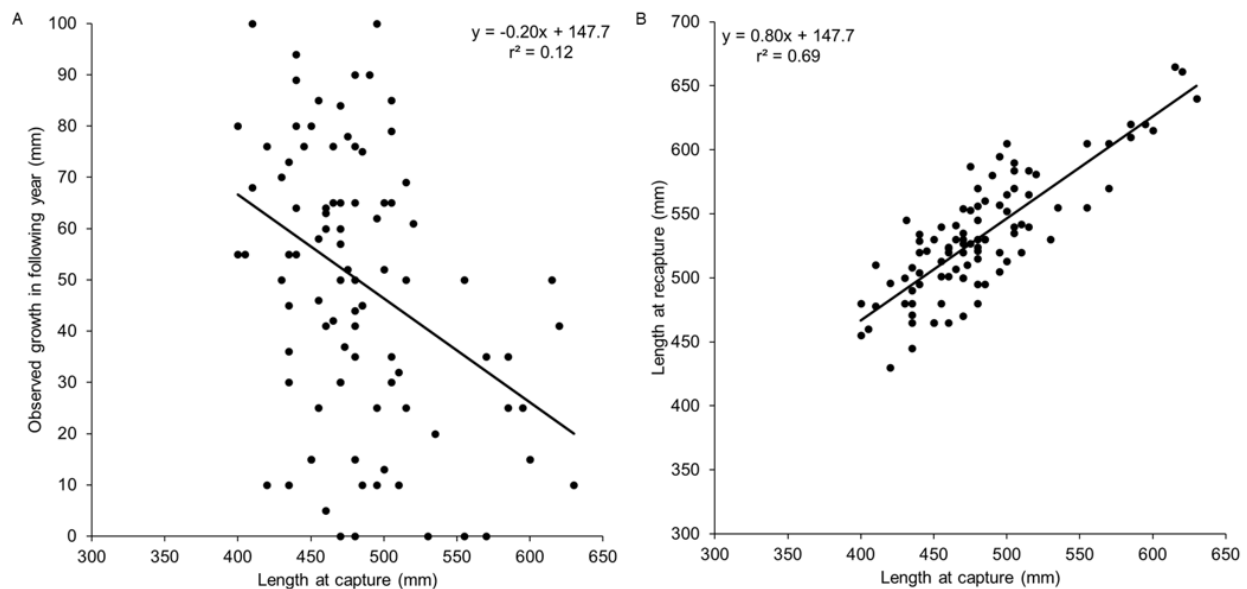

Figure 7. (A) Observed annual growth and (B) length at capture and recapture of Dolly Varden from the Rat River based on mark and recapture studies between 2009 and 2014.

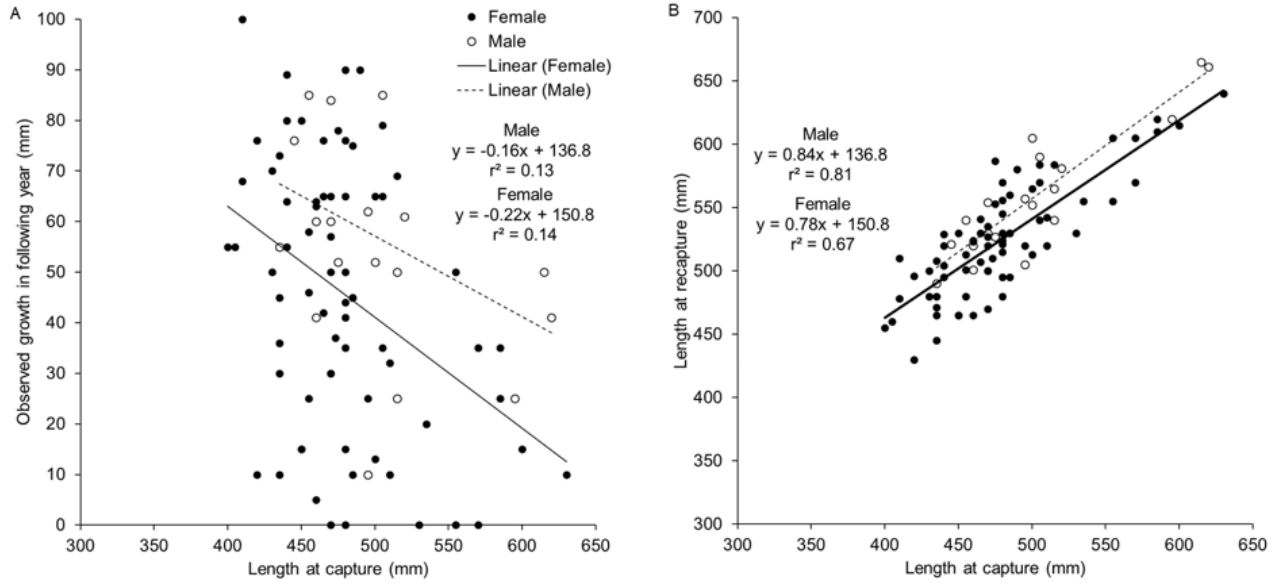

Figure 8. (A) Observed annual growth and (B) length at capture and recapture of female and male Dolly Varden from the Rat River based on mark and recapture studies between 2009 and 2014.

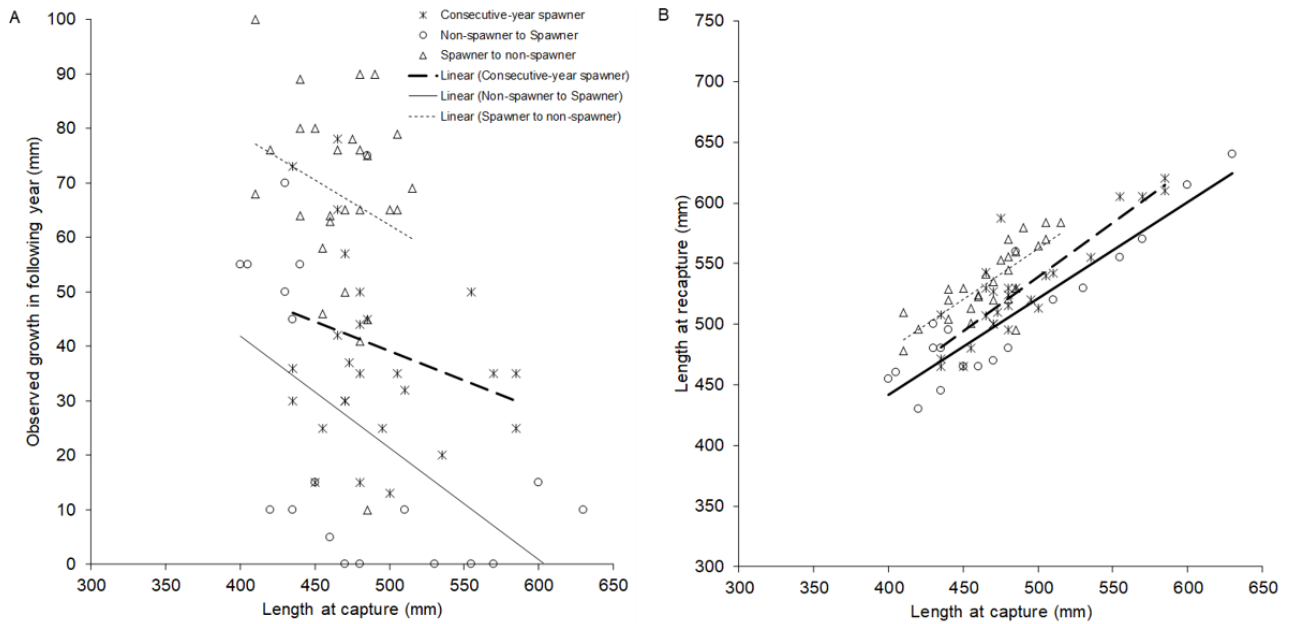

Figure 9. (A) Observed annual growth and (B) length at capture and recapture of female Dolly Varden from the Rat River among categories of reproductive status from one year to the next based on mark and recapture studies between 2009 and 2014.

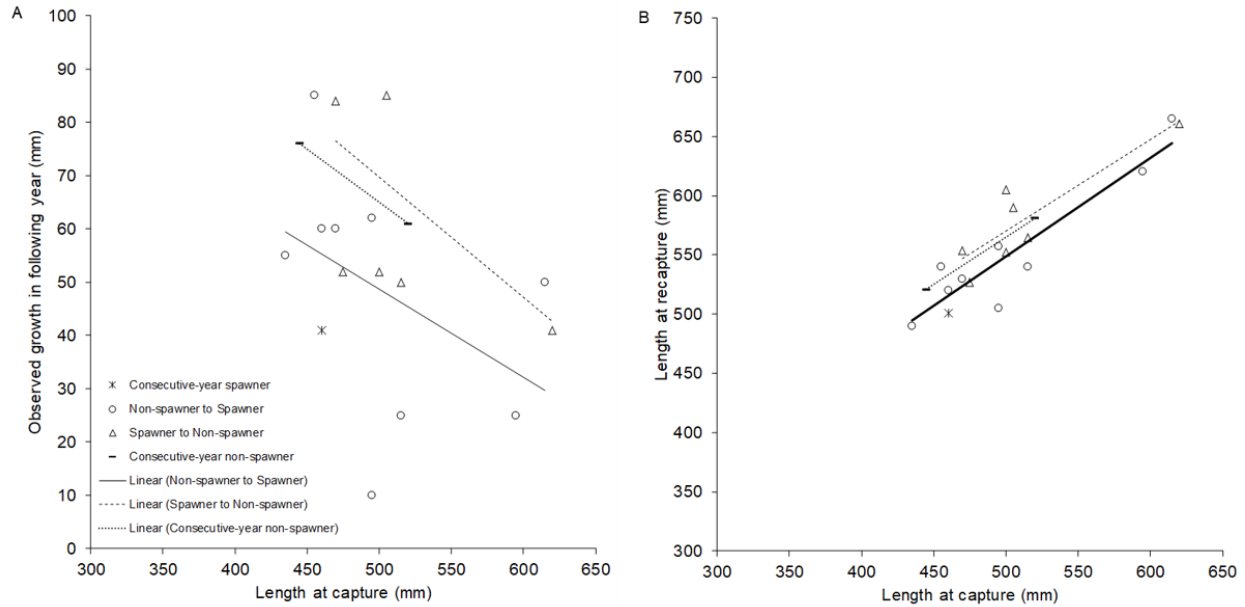

Figure 10. (A) Observed annual growth and (B) length at capture and recapture of male Dolly Varden from the Rat River among categories of reproductive status from one year to the next based on mark and recapture studies between 2009 and 2014.

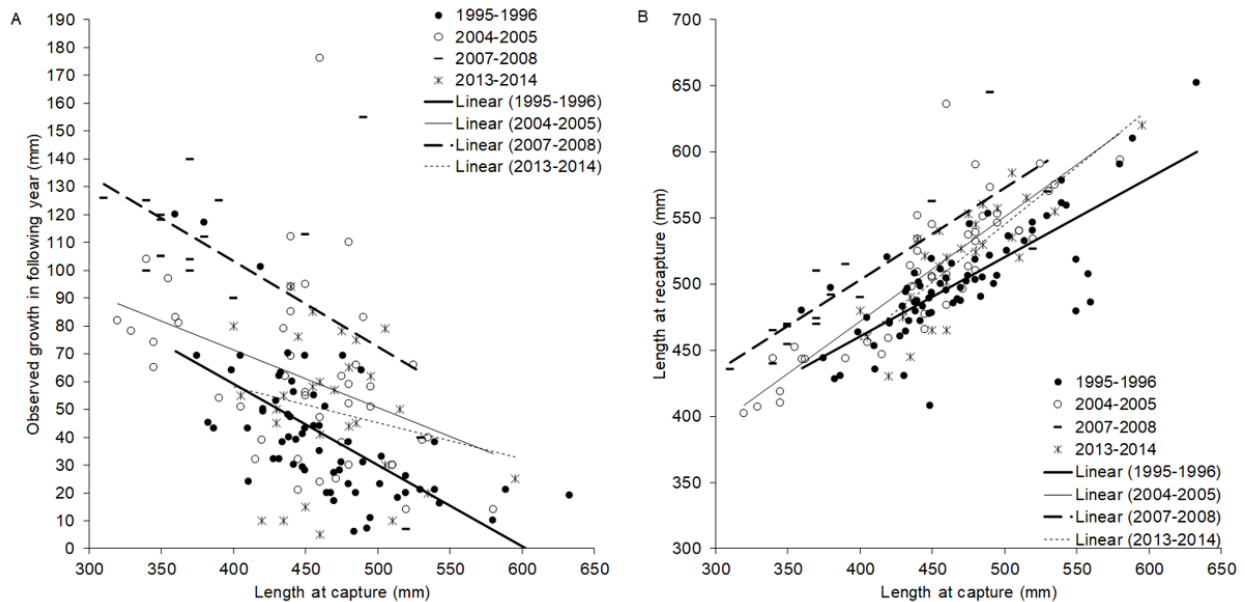

Figure 11. (A) Observed annual growth and (B) length at capture and recapture of female Dolly Varden from the Rat River among years based on mark and recapture studies between 2009 and 2014. Years 1997-1998 and 2001-2002 were not examined due to low sample size of recaptures.

### Repeat and skip spawning, and proportion of non-spawners and spawners

Based on 55 females and 8 males, 50.9% of females and 12.5% of males tagged as spawners were recaptured in spawning condition the following year in the Rat River Harvest Monitoring Program or seining program (Table 4). Males were twice as likely to skip spawning in the following year (87.5%) compared to females (49.1%).

Table 4. Frequency among categories of annual change in reproductive status for female, male, and sex unknown anadromous Dolly Varden from the Rat River based on the recapture of tagged fish in the Rat River Harvest Monitoring Program and by seining at the spawning and overwintering area between 2010 and 2014.

Annual change	Female	Male	Unknown
Non-spawner to Non-spawner	-	2	5
Non-spawner to Spawner	19	9	-
Spawner to Spawner	28	1	-
Spawner to Non-spawner	27	7	-
<b>Total (n)</b>	<b>74</b>	<b>19</b>	<b>5</b>

Female spawners were the most abundant (50-70% of total catch) Dolly Varden captured in the lower reach of Fish Creek at the end of September between 2009 and 2012 and were four to nine times more abundant than male spawners across years (Table 5, Figure 12). The proportion of female spawners in the sample during this period of time decreased from 70% in 2009 to ~ 33% in 2013 and 2014 (Pearson correlation  $r = -0.95$ ,  $p = 0.003$ ). The proportion of male spawners varied among years (3.7 - 14% of the catch) and although the proportion had increased during 2009-2014, this trend was not statistically significant. Concurrent with the decline in female spawners was an increase in the proportion of non-spawners from a low of 19.4% in 2009 to a high of ~ 60% in 2013 and 2014 (Pearson correlation  $r = 0.89$ ,  $p = 0.02$ ) (Figure 12). Spawners (male and female) made up 70-80% of the sample in 2009 and 2011, which is a higher proportion than observed in other years.

Table 5. Percent and frequency (in brackets) of live-sampled anadromous Dolly Varden from the Rat River identified as non-spawners, and female and male spawners captured at the lower (above dashed line) and upper reaches (below dashed line) of Fish Creek. Fish were captured using a seine net at spawning and overwintering locations in late September to early October between 1995 and 2014. The ratio of female to male spawners, and proportion of spawners are calculated, and the number of juveniles (pre-smolt) (FWJ,  $\leq 230$  mm) and resident life-history type (RES) are included.

Year	Non-spawner	Female spawner	Male spawner	Total (n)	F:M spawner	% spawner	FWJ (n)	RES (n)
2014	59.6 (307)	33.2 (171)	7.2 (37)	515	4.6:1	40.4	2	0
2013	62.2 (250)	34.1 (137)	3.7 (15)	402	9.1:1	37.8	10	0
2012	40.1 (158)	48.0 (189)	11.9 (47)	394	4.0:1	59.9	0	0
2011	28.0 (44)	58.6 (92)	13.4 (21)	157	4.4:1	72.0	0	0
2010	38.6 (182)	55.4 (261)	5.9 (28)	471	9.3:1	61.4	0	0
2009	19.4 (91)	70.0 (329)	10.6 (50)	470	6.6:1	80.6	0	0
2008	94.1 (491)	5.6 (29)	0.4 (2)	522	14.5:1	5.9	0	2
2007	75.5 (326)	22.5 (97)	2.1 (9)	432	10.8:1	24.5	0	0
2004	36.2 (100)	62.3 (172)	1.4 (4)	276	43:1	63.8	0	1
2001	61.4 (254)	35.5 (147)	3.1 (13)	414	11.3:1	38.6	*	0
1997	46.5 (207)	43.8 (195)	9.7 (43)	445	4.5:1	53.5	0	0
1995	33.8 (150)	59.7 (265)	6.5 (29)	444	9.1:1	66.2	0	0
2014	0	32.8 (8)	68.0 (17)	25	0.5:1	100	15	31
2013	1.6 (1)	75.8 (47)	22.6 (14)	62	3.4:1	98.4	26	154

\* n = 5  $\leq$  280 mm classified as non-spawner may have been misidentified and could have been FWJ.

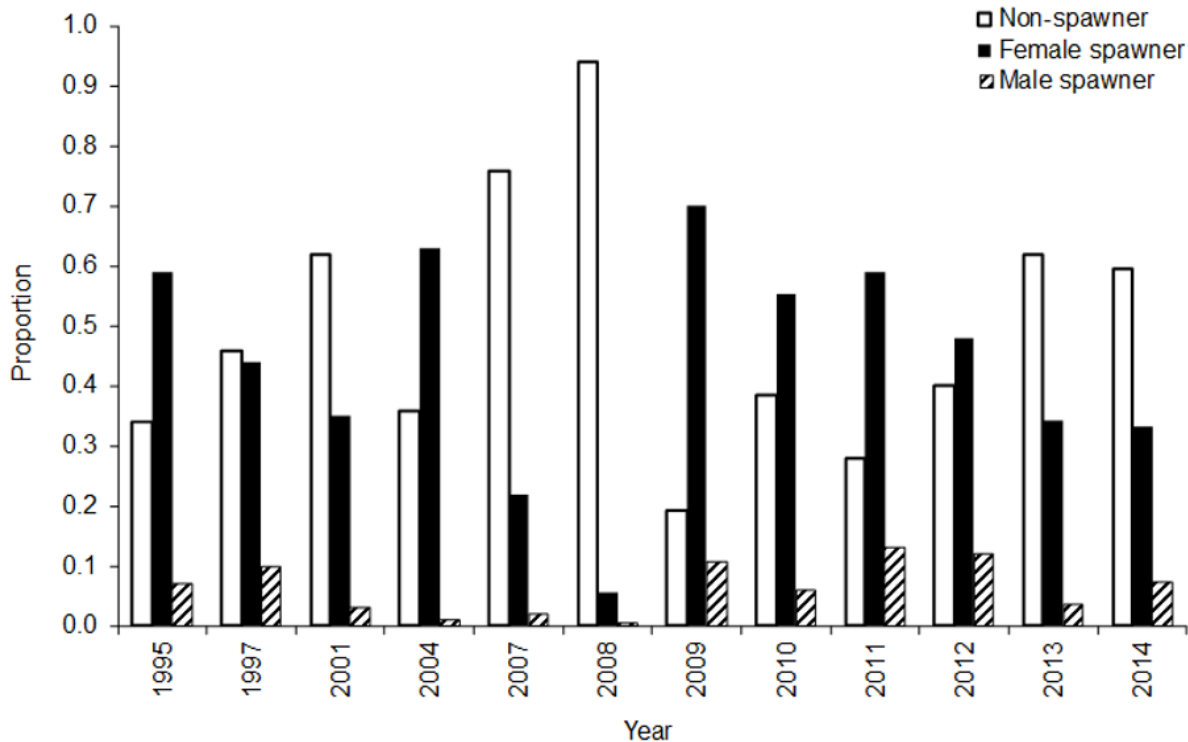

Figure 12. Proportion of anadromous Dolly Varden from the Rat River captured by seine net at the spawning and overwintering area (lower reach) in September between 1995 and 2014 and identified as non-spawners, female spawners and male spawners.

Although sample sizes were low, the upper reaches of Fish Creek had a higher proportion of male spawners, a near-absence of non-spawners, and the presence of a large number of resident life history (fork length range = 163-310 mm) and freshwater (pre-smolt) juveniles (fork length range = 150-230 mm) Dolly Varden (Table 5). Two spawning fish tagged in the lower reach (a male in 2009 and a female in 2010) were recaptured spawning in the upper reach in 2013. Two non-spawners tagged in the lower reach in 2013 (455 mm and 460 mm) were recaptured in the upper reach in 2014 as male spawners, while a female spawner tagged in the upper reach in 2013 was recaptured in spawning condition the following year in the lower reach.

## DISCUSSION

### POPULATION ABUNDANCE

Abundance estimates generated from the two different recapture methods in 2009, 2010, and 2013 were generally consistent with one another. These similarities in overall estimates and direction of trend provides confidence that population abundance has increased in recent years. However, the narrower confidence intervals from the recaptures obtained from seining suggests this method may provide a more precise estimate. It is uncertain why the estimate using recaptures from the harvest monitoring program was consistently higher than the estimate using recaptures from seining. The estimates for 2013 suggest the population has increased to approximately 12,000-15,000 from 2,900 in 2014, nearly 10 years later. Although relatively high in 2013, the population is presumably not as high as it was prior to the 1980s based on traditional knowledge reports for this population (e.g., obtaining 700 fish after two sweeps of a net at the Fish Hole; Benson 2010).

---

## BIOLOGY

The seining program revealed the presence of a wide range of sizes present at the spawning and overwintering location in the fall. The largest sizes (~ 700-730 mm) of Dolly Varden ever observed while seining in September were captured between 2012 and 2014. The presence of larger sizes in the stock in recent years was also noted by Gallagher et al. (2020) who attributed increased sizes to an improved survival rate. Years where a high proportion of < 400 mm non-spawners (i.e., 2007, 2008, 2012, and 2014) were also captured during seining suggests an increase in the proportion of juveniles in the subsistence fishery in those years. The annual variability in the proportion of small sized non-spawners captured in the seine net suggests inter-annual variation in year-class strength.

The higher growth demonstrated by females that skip spawning compared to those that spawn in consecutive years is consistent with the findings of Sandstrom et al. (2009). Evidently, female spawning frequency produces trade-offs with respect to opportunity for growth. The increased growth of consecutive-year spawning females in 2009-2014 compared to 1995-1996 is similar to results from Sandstrom et al. (2009), who found higher growth in 2004-2005 compared to 1995-1996. Sandstrom et al. (2009) speculated that differences in growth between 2004-2005 and 1995-1996 were a result of earlier ice breakup along the Beaufort Sea coast which would have improved the somatic condition of the fish and facilitated improved growth. The lower growth observed in 2009-2014 compared to 2004-2005 could be in response to variation in feeding opportunity or diet quality associated with the timing of ice breakup between these time periods, although more quantitative evaluation is required to assess this (see Harwood et al. 2009).

Life history differences between sexes are likely a product of divergences in costs and benefits associated with reproduction. Compared to females, males attained larger sizes, grew faster, experienced lower survival (Gallagher et al. 2020), and skipped spawning more often. These differences in the context of a stock that endures a long freshwater migration and exhibits intense breeding competition (Fleming and Reynolds 2004), suggests males invest heavily into growth to defend territory and females in optimal spawning locations. The proportion of male spawners observed while seining at the spawning and overwintering area increased somewhat during 2009-2014 compared to 2001-2008. Although speculative, one possibility is a change in the proportion of males in the population that adopt either a resident (male biased) or anadromous (female biased) life history tactic. Adopting either life history tactic could be influenced by a combination of factors, including polygenic traits, and metabolic and environmental factors (e.g., its effect on food availability) affecting growth thresholds (e.g., increased growth at an early age) that allow individuals to mature early without resorting to anadromy (Fleming 1996, Gross 1996, Forseth et al. 1999, Wysujack et al. 2009). Research is necessary to determine whether any combination of these factors have an effect on life history tactics adopted by juvenile male Dolly Varden in the Rat River, explaining changes in the proportion of anadromous spawning males in the population.

Although the declining trend in the proportion of female spawners observed between 2009 and 2014 could be interpreted as a signal that the stock is in decline, these values overlapped with those from previous years when abundance was relatively high (1995 and 1997). Regardless, the proportion of female spawners in the seine sample in recent years suggests the female spawning stock biomass was high enough to contribute to an increase in total abundance between 2009 and 2014.

The upper reach of Fish Creek appears to provide high quality habitat for spawning, given the relatively large number of residents (all in spawning condition) and high proportion (albeit in lower numbers compared to the lower reach) of anadromous spawners that were captured. Furthermore, the large number of pre-smolt juveniles indicates that the location provides

---

important rearing habitat. This study is the first to report a high number of the resident life history in Fish Creek after Sandstrom et al. (2009) lamented their scarcity in the river system based on sampling conducted in the lower reach. If the upper reach is an ideal location for spawning and given the detection of tagged spawning fish utilizing both upper and lower habitats among years, additional research should be conducted to evaluate the extent to which anadromous fish utilize the upper reach during spawning (presumably mid-September) before moving downstream to the lower reach and becoming susceptible to seining efforts at the end of September when they are in a post-spawning state.

## CONCLUSION

The time-series of information from the mark-recapture program based on seining at the spawning and overwintering area in Fish Creek indicates the Rat River population of Dolly Varden is currently stable and sustainably harvested. The increased abundance and the high proportion of large-size fish and spawners suggest the level of subsistence harvest since 2004 has been suitable for improving stock status. Other sources of information for Dolly Varden from the Rat River corroborate this interpretation (DFO 2017, Gallagher et al. 2020). The mark-recapture program has provided an important time-series of fishery independent data useful for the assessment of the population and for improving our understanding of the biology of Dolly Varden from the Rat River.

## ACKNOWLEDGEMENTS

The seining/mark-recapture program on the Rat River between 2009 and 2014 was supported by Fisheries and Oceans Canada (DFO Inuvik and Larry Dow), Gwich'in Renewable Resources Board (GRRB and Wildlife Studies Fund), and the Polar Continental Shelf Program. We acknowledge assistance in the field by Kevin Bill (2009, 2010), Matt Kowalchuk (2009), and Ellen Lea (2012, 2013) (DFO); Amy Amos (2011) and Kris Maier (2013, 2014) (GRRB); Lazarus Edwards (2011), Sterling Firth (2012), Dale Semple (2012), Dennis Semple (2013), Chris Semple (2014), Edward McLeod (2014) (Aklavik); and Andy Seitz (University of Alaska Fairbanks) (2014). We are grateful for the safe flights provided by Canadian Helicopters and Great Slave Helicopters over the years. We also acknowledge the support and direction provided by the Rat River Working Group.

## APPENDIX 1. BIOLOGICAL INFORMATION FOR DOLLY VARDEN FROM THE RAT RIVER STOCK

Table A1.1 Biological information for Dolly Varden from the Rat River stock (Fish Creek) captured using a seine net in the fall between 2008 and 2014 for t-bar tagging programs. Data from 1995 and 2007 are available in Sandstrom et al. (2009). Data included here includes life history (anadromous, resident, freshwater juvenile, young-of-the-year), date of capture (dd-month-yy), seine # (sequential order of seine net deployed in pools), sex (male [M], and female [F]), reproductive status (spawner or non-spawner), tag ID (individually unique numbers), injury (scar = old injury that is healed, or wound = recent injury; size is > 2.5 cm and incurred from predators) (not recorded in 2008), injury location (combination of anterior/ posterior and ventral/ dorsal), recapture (confirms if sample was previously tagged), recapture tag ID, tag colour (2008 = no tags, 2009 = blue, 2010 = yellow, 2011 and 2012 = no tags, 2013 = orange and yellow, 2014 = blue) [note, green tags deployed in 2007], sampling area (general location where seining occurred; lower and upper Fish Cr. correspond with 'lower reach seining site' and 'upper reach seining site', respectively in Figure 1). It is noted that a 220 mm female in spawning condition (September 27, 2014 in seine #13) was confirmed to be a resident life history using otolith strontium analysis.

## APPENDIX 2. STATISTICAL TEST RESULTS

*Table A2.1 Mann-Whitney test (U) or two-sample t-test examining for differences in length between sampling years for anadromous Dolly Varden from the Rat River identified as female (bottom diagonal) and male (top diagonal) spawners and that were captured by seining at the spawning and overwintering area (lower reach) between 2009 and 2014. Statistically significant results ( $p \leq 0.05$ ) are in bold.*

Year	2014	2013	2012	2011	2010	2009
2014	-	<b>t = -3.6 (1,361), p = 0.01</b>	<b>t = -5.2 (1,99), p &lt; 0.00</b>	<b>t = -6.5 (1,73), p &lt; 0.00</b>	t = -1.1 (1,80), p = 0.26	t = -2.0 (1,506), p = 0.84
2013	<b>U = 12261, p &lt; 0.00</b>	-	<b>t = -3.2 (1,74), p &lt; 0.00</b>	<b>t = -4.6 (1,48), p &lt; 0.00</b>	t = -0.6 (1,55), p = 0.95	t = -0.9 (1,77), p = 0.35
2012	<b>U = 8649, p &lt; 0.00</b>	<b>U = 12638, p &lt; 0.00</b>	-	t = -1.5 (1,66), p = 0.13	<b>t = 3.6 (1,73), p &lt; 0.00</b>	<b>t = 5.7 (1,95), p &lt; 0.00</b>
2011	<b>U = 4767, p &lt; 0.00</b>	<b>U = 6820, p &lt; 0.00</b>	U = 7888, p = 0.21	-	<b>t = 6.8 (1,47), p &lt; 0.00</b>	<b>t = 8.9 (1,69), p &lt; 0.00</b>
2010	<b>U = 20655, p = 0.04</b>	<b>U = 20301, p &lt; 0.00</b>	<b>U = 13930, p &lt; 0.00</b>	<b>U = 7556, p &lt; 0.00</b>	-	t = 1.3 (1,76), p = 1.9
2009	U = 26489, p = 0.06	<b>U = 23742, p &lt; 0.00</b>	<b>U = 15535, p &lt; 0.00</b>	<b>U = 8583, p &lt; 0.00</b>	U = 40936, p = 0.3	-

*Table A2.2. Mann-Whitney test (U) or two-sample t-test examining for differences in length between sampling years for anadromous Dolly Varden from the Rat River identified as non-spawners that were captured by seining at the spawning and overwintering area (lower reach) between 2010 and 2014. Statistically significant results ( $p \leq 0.05$ ) are in bold.*

Year	2014	2013	2012	2011	2010
