## Foreword

This series documents the scientific basis for the evaluation of aquatic resources and ecosystems in Canada. As such, it addresses the issues of the day in the time frames required and the documents it contains are not intended as definitive statements on the subjects addressed but rather as progress reports on ongoing investigations.

#### Abstract

Fisheries and Oceans Canada conducts an annual multidisciplinary survey in the Estuary and northern Gulf of St. Lawrence. The objectives of this survey are varied; assess the biodiversity of species found near the bottom; estimate the abundance of groundfish and invertebrates; assess physical and biological (phytoplankton and zooplankton) oceanographic conditions; monitor the pelagic ecosystem; and collect samples for various research projects. In 2020, the survey was conducted between August 12 and September 5 on board the CCGS Teleost. Due to the context of the Covid-19 pandemic, the number of days at sea and the number of scientists on board the ship had to be reduced. The survey successfully carried out 147 trawl tows as well as 66 CTD water column casts, and 34 zooplankton samples.

This report presents the results of the 147 tows. In total, 78 fish taxa and 206 invertebrate taxa were identified during the mission. Historical perspectives (catch rates, spatial distribution and length frequency) are presented for 25 taxa. These commercial fishery-independent data will be used in several stock assessments including cod (Gadus morhua), redfish (Sebastes spp.), Greenland halibut (Reinhardtius hippoglossoides), Atlantic halibut (Hippoglossus hippoglossus), witch flounder (Glyptocephalus cynoglossus) and northern shrimp (Pandalus borealis).

A preliminary analysis of water temperature data collected in 2020 shows that conditions have warmed at 150 m and deeper, reaching new records since 1915 at 200 and 300 m . The cold intermediate layer was warmer in 2020 than in 2019 except in the Estuary where it remained stable. Surface waters were also warmer than normal, by $1.5^{\circ} \mathrm{C}$, in July-August.

## INTRODUCTION

Fisheries and Oceans Canada conducts an annual bottom trawl survey in the Estuary and the northern Gulf of St. Lawrence. This is a multi-species, commercial fishery-independent survey. Its purpose is to assess the ecosystem with consistent and standardized protocols. This survey examines, among other things, spatial and temporal changes in the distribution and relative abundance of fish and their assemblages. It also aims to gather information on the biological parameters of commercial species.

The main objectives are to:

1. assess groundfish and Northern Shrimp population abundance and condition;
2. assess environmental conditions;
3. conduct a biodiversity inventory of benthic and demersal megafauna;
4. assess phytoplankton and mesozooplankton abundance;
5. monitor the pelagic ecosystem;
6. conduct an inventory of marine mammals (cancelled in 2020);
7. conduct an inventory of seabirds (cancelled in 2019 and 2020);
8. collect samples for various research projects.

In 2020, the survey was conducted between August 12 and September 5 onboard the CCGS Teleost (mission IML-2020-012). This mission took place in the context of the Covid-19 pandemic. Sanitary measures had to be put in place so that the mission could be carried out.

First, the number of days at sea has been reduced from 33 to 25 days so that the science crew boarding coincides with the crew change of the CCGS Teleost. So we were going to create a "bubble" with the two crews throughout the duration of the mission. It was therefore not possible to disembark or make crew changes. Normally, at mid-survey there is a change of science team. In the end, following the reduction in the duration of the mission, 147 fishing stations were successfully carried out, while on average around 190 stations are made.

The science crew has also been reduced from 15 to 9 scientists. Observers for marine mammals and seabirds did not participate to the survey, so the objectives of inventorying these species could not be achieved. The number of oceanographers has been reduced from 2 to 1. There is normally an oceanographer on duty at all times. With this reduction, oceanographic activities had to be reduced and focused on daylight hours. In the end, the number of vertical water column profiles (CTDs) was reduced by approximately $33 \%$ and the numbers of zooplankton samples were reduced by more than $50 \%$. The number of scientists on the fishing team has been reduced by 3 people. This reduction has resulted in a review of the fish and invertebrate sampling protocols. The number of biological characteristics measured on fish and invertebrates has been reduced, for example, there have been no individual weights collected for non-commercial species, no individual length measurements of sea pens, otoliths of Greenland halibut and witch flounder were not collected. In addition, the number of protocols for collecting samples for DFO and academia research projects has been reduced. Finally, the shrimp samples were not measured during the mission but were brought back to the laboratory and were analyzed in the fall.

## SURVEY DESCRIPTION

The survey covers the waters of the Laurentian Channel and north of it, from the Lower Estuary in the west to the Strait of Belle Isle and the Cabot Strait in the east, namely, the Northwest Atlantic Fisheries Organization (NAFO) divisions 4R, 4S and the northern part of 4T (Figure 1). Since 2008, the coverage of division 4T has been increased in the upstream part of the Lower Estuary in order to sample the depths between 37 and 183 m . The study area is $118,587 \mathrm{~km}^{2}$.

A stratified random sampling strategy was used for this survey. This technique consists in subdividing the study area into more homogeneous strata. The area was divided into 54 strata, which were divided based on depth, NAFO division and substrate type (Figure 2). A total of 200 trawl stations was initially allocated in the study area, which is a number proportional to the stratum surface, with a minimum of two stations per stratum. The tow positions were chosen randomly within each stratum. Since 2014, a new rule was added to respect a minimum distance of 10 km between stations in the same stratum.

The fishing gear used on the CCGS Teleost is a four-sided Campelen 1800 shrimp trawl equipped with a Rockhopper footgear ("bicycle") (McCallum and Walsh 2002). The trawl lengthening and codend are equipped with a $12.7-\mathrm{mm}$ knotless nylon lining. Standard trawling tows last 15 minutes, starting from the time the trawl touched the sea floor as determined by the Scanmar ${ }^{\top M}$ hydroacoustic system. Towing speed is 3 knots. Information on trawl geometry (horizontal spread of the doors and wings, vertical opening of the trawl, depth) was recorded for each tow using Scanmar ${ }^{\top \mathrm{M}}$ hydroacoustic sensors mounted on the fishing gear.

In 2020, 147 fishing stations were successfully completed ( 52 in 4R, 62 in 4S and 33 in 4T), which represent 40 stations less than what has been achieved on average since 1990 (Annex 1). The decrease in the number of stations completed was caused by a shortening in the duration of the survey by 8 days. A lot of effort was made to cover the entire study area. Eleven strata were not sampled with a minimum of two stations (Figure 3, Appendix 1). These partially or uncovered strata were distributed throughout the study area and not located in a particular sector.

For each fishing tow, the catch was sorted and weighed by taxa; biological data were then collected on a sub-sample. For fish, crab and squid, size and weight were gathered by individual. For some species, sex, maturity, and the weight of certain organs (stomach, liver, gonads) were also evaluated. Count of soft rays of the anal fin for redfish was conducted to separate the two species. Otoliths were saved for cod and Atlantic halibut to conduct ageing analysis. A sample of approximately 2 kg of shrimps was frozen for laboratory analysis at the Maurice Lamontagne Institute where the sample was sorted and weighed by species and by stage of maturity for the northern shrimp. The shrimps were measured individually. The other invertebrates were counted (no individual measurements) and photographed. The photos are archived in a photo catalogue with associated keywords (taxonomic identification, station description, date, etc.).
Since 2001, digital photos have supported an increased effort in the identification of species. These additional efforts have targeted fish since 2004 (Dutil et al. 2009) and invertebrates since 2005 (Nozères et al. 2014). An identification guide for marine fishes in the estuary and northern Gulf of St. Lawrence (Nozères et al. 2010), a shrimp atlas (Savard and Nozères 2012) and a guide for invertebrates (Nozères and Archambault 2014) were used during the mission to identify most taxa. The taxon codes and their names follow the list of Miller and Chabot (2014), with annual updates according to the World Register of Marine Species (WoRMS).
Additional samples were taken for various scientific projects:
9. Water samples for genetic analysis of environmental DNA;
10. Samples of herring, capelin and mackerel for maturity determination;
11. Beluga and marine mammal preys (several fish species and northern shrimp) in order to follow the evolution of isotopic signatures of key species in the St. Lawrence ecosystem;
12. Stomachs of several fish species in order to describe their diet;
13. Samples of small demersal fish;
14. Blood samples from Atlantic halibut and Greenland halibut to characterize the state of health of the ecosystem from molecular markers;
15. Small redfish (< 11 cm ) for genetic identification of the species (Sebastes fasciatus and $S$. mentella) and the population of new cohorts observed in the Gulf;
16. Monitoring redfish growth from the 2011 cohort;
17. Atlantic halibut, Greenland halibut and thorny skate gonad samples to determine stage of maturity;
18. Squid samples to study its trophic role in the ecosystem;
19. Sponges (Porifera) for identifications;

Oceanographic conditions such as temperature, conductivity (salinity), turbidity, dissolved oxygen, luminosity and fluorescence were sampled during this survey. A total of 55 vertical profiles of the water column were done at the fishing stations and 11 more on extra stations that fall under the Atlantic Zone Monitoring Program (AZMP). The various equipment, CTD SeaBird 911Plus ${ }^{\text {TM }}$, dissolved oxygen sensor (SBE 43), photometer (Biospherical) and fluorometer (EcoFLNTU Wetlabs) were coupled to the rosette of Niskin bottles. For each profile obtained using the rosette, water samples were also taken at several depths to determine their salinity, pH , dissolved oxygen concentration (Winkler titration), nutritive salt content (nitrite, nitrate, phosphate, silicate) and chlorophyll content. In addition, a CTD SBE 19P/us ${ }^{\text {TM }}$ device (temperature and salinity), coupled to a dissolved oxygen sensor (SBE 63), was also installed on the back of the trawl, thereby allowing oceanographic data to be collected for the 147 fishing tows.

To study of zooplankton distribution and biomass for the study area consisted of vertical tows from the sea floor to the surface using a zooplankton net ( $202 \mu \mathrm{~m}$ ) at 34 stations.
Water column hydroacoustic data at four frequencies (38, 70, 120 and 200 kHz ) were recorded using a SIMRAD ${ }^{T M}$ EK60 echosounder during the entirety of the mission. These data will be used to develop a three-dimensional database to map the pelagic ecosystem.

## DATA ANALYSIS

The analysis of 2020 abundance and biomass data was integrated into the combined annual summer survey series initiated in 1990. These combined series were developed following a comparative study between the two vessel-gear tandems (1990-2005: CCGS Alfred Needler URI 81'/114' trawl; 2004-2020: CCGS Teleost - Campelen 1800 trawl) to establish specific correction factors for about twenty species caught (Bourdages et al. 2007). Results from this study led to an adjustment of Needler catches into Teleost equivalent catches.

Given that over the years, some strata were not sampled by a minimum of two successful tows (Appendix 1), a multiplicative model was used to estimate their catch rate indexes in number and weight. This model provided a predicted value for strata with less than two tows with the data of the current year and the previous three years. Thus, indicators presented for the series are representative of a standard total area of $116115 \mathrm{~km}^{2}$, the sum of the area of all strata. In
addition, reference points were also added to the catch rate figures. The solid line represents the 1990-2019 period average (long-term average) and the two dotted lines associated to the mean $\pm 0.5$ standard deviation corresponding respectively to the upper and lower reference limits.
Note that the distinction between the two redfish species, S. fasciatus and S. mentella, is based on the analysis of the soft anal fin rays count and the depth of capture of individuals (H. Bourdages, DFO Mont-Joli, pers. comm.).
Length frequency distributions are presented in two different forms. The first figure shows the distribution for the last two years of the series plus the average distribution for the 1990-2019 period (long-term average distribution). Frequency values are expressed as the average number of individuals caught per tow in increment of 1 cm , except for the northern shrimp $(0.5 \mathrm{~mm})$ and Atlantic halibut ( 3 cm ). The second figure represents the length distributions in length mean per class length for each year of the historical surveys series (1990 to 2020).
The geographical distribution of catches by weight per tow (kg/15 minutes tow, except for sea pens number/15 minutes tow) was made for periods of four or five years. The interpolation of CPUE (catch per unit of effort) was performed on a grid covering the study area using a ponderation inversely proportional to the distance ( R version 2.13.0, Rgeos library; R Development Core Team 2011). The isoline conto urs were then plotted for four CPUE levels which approximate the $20^{\text {th }}, 40^{\text {th }}, 60^{\text {th }}$ and $80^{\text {th }}$ percentiles of the non-zero values. The catch rate distribution for the 2019 survey only is also presented in a bubbles type map.

The preliminary results for the abundance and biomass indices, the catch rate distribution maps, and the size frequency distributions for about 25 taxa commercially fished are presented at figures 5 to 62 . These results are preliminary and must be considered as such until validations and laboratory analyses have been completed.

The distribution of total species richness and species richness of 3 taxonomic groupings is presented in figures 63 to 66 . Species richness is expressed as the number of species collected, total or per grouping, at each station in 2020. Taxonomic groupings were made to observe specifically the distribution of species richness for species with similar ecological characteristics: fishes, shrimp and invertebrates (excluding shrimp).

The average weight per tow for 57 taxa of fish and 99 taxa of invertebrates is given in figures 67 and 68. In these figures, a color code is used to represent the difference between the CPUE in a given year and the average CPUE in the time series divided by the standard deviation of this average for each taxon.
The catches per tow for fish taxa are available on the St. Lawrence Global Observatory (SLGO).
Finally, Appendix 2 provides a list of all taxa, vertebrates and invertebrates, caught among the 147 successful tows achieved during the 2020 survey. The occurrence, or the number of tows where the species was identified, as well as the total catch, by weight and numbers, are also presented. The number of specimens measured per taxon and some descriptive statistics for the length parameter are also presented in Appendix 3.

## RESULTS

Warning: the bottom trawl survey is designed to sample demersal species. However, catches may also include pelagic species and species associated with coastal or rocky habitats which are more difficult to trawl. Although these taxa are found in catches, they have a low catchability by trawl net. Some caution is required when interpreting the results obtained for these taxa.

## BIODIVERSITY

In total, 78 fish taxa and 206 invertebrate taxa were identified in 2020 (Appendix 2).
In 2020, the biomass of the two redfish species combined accounted for $90 \%$ of the biomass of all captured organisms, while it averaged 15\% between 1995 and 2012 (Figure 4). The Atlantic redfish (Sebastes mentella) constituted, alone, more than $85 \%$ of the catches made during the survey.

Species richness is particularly high near the coasts such as north of Anticosti, the Strait of Belle Isle and southwest of Newfoundland (Figure 63). The Strait of Belle-Isle is particularly diverse in terms of invertebrates (Figure 65) and shrimps (Figure 66), many species of which cannot be found anywhere else. This high richness is imputable to the Labrador Current entering the Gulf by the Strait of Belle Isle which allows the establishment of arctic species in this area. Similarly, areas rich in fish species are seen at the Cabot Strait at great depths (Figure 64). At these stations, the presence of rare species coming from the depths of the Atlantic can be observed.

## Fish

The abundance and the biomass of the black dogfish (Centroscyllium fabricii) have been above average for the past nine years (Figures 5 to 7 ).

Capelin (Mallotus villosus) was mainly distributed from the Estuary to Anticosti Island during the 2020 survey. We note its almost absence in the catches along the North Shore east of Havre-Saint-Pierre and in the Strait of Belle Isle whereas capelin is normally a regular catch in these regions (Figure 8).
For the past thirteen years, abundance and biomass of Atlantic halibut (Hippoglossus hippoglossus) has remained above the series average (Figures 9 to 11).

The abundance and biomass of Greenland halibut (Reinhardtius hippoglossoides) are increasing from 2019. In 2020, abundance is slightly above average and biomass is equal to average. The size frequency distributions indicate that the 2019 cohort ( 16 cm mode) is below the series mean in abundance while the abundance of fish 22 cm to 39 cm is above this mean (Figures 12 to 14).
The lumpfish (Cyclopterus lumpus) was a rare but regular catch in this survey. Abundance and biomass have been above the series average since many years (Figures 15 to 17).
Atlantic herring (Clupea harengus) was a frequent catch in this survey and was distributed throughout the northern Gulf of St. Lawrence with the exception of the depths of the Laurentian Channel. The highest catches are observed along the west coast of Newfoundland (Figure 18).
Atlantic wolffish (Anarhichas lupus) and spotted wolffish (Anarhichas minor) were caught on 24 and 6 occasions, respectively in 2020. These catches were mainly distributed in the northern eastern part of the Gulf of St. Lawrence (Figures 19 and 20).
Since 2007, silver hake (Merluccius bilinearis) has been more common in the northern Gulf, before it was only occasionally observed (Figures 21 to 23).
The abundance and biomass of the longfin hake (Phycis chesteri) are near the average in 2020 (Figures 24 to 26).
The abundance and biomass of white hake (Urophycis tenuis) has been above or equal the average since eight years (Figures 27 to 29).

In 2020, the abundance and biomass indices of cod (Gadus morhua) increased, the abundance index is above average while the biomass index is similar to the average of the series. A length frequency mode is observed from 22 to 29 cm (juvenile cod). The geographic distribution of catches in 2020 is comparable to previous years (Figures 30 to 32).
American plaice (Hippoglossoides platessoides) was frequently caught and its abundance is stable and above average (Figures 33 to 35).
Witch flounder (Glyptocephalus cynoglossus) was frequently caught. The strong cohorts from 2007 and 2009 have contributed to the increase in biomass; these fish are now larger than 30 cm (Figures 36 to 38).
Thorny skate (Amblyraja radiata) and smooth skate (Malacoraja senta) were both very frequently caught. The abundance of thorny skate is increasing and decreasing for smooth skate (Figures 39 to 44).

Arctic cod (Boreogadus saida) is a small cold water demersal fish. Catches in recent years have been made in the Estuary, along the North Shore and on the west coast of Newfoundland (Figures 45 to 46).

Acadian redfish abundance (Sebastes fasciatus) is near the average of the time series, while biomass is above the latter (Figures 47 to 49).
Three strong cohorts (2011, 2012 and 2013) of Atlantic redfish (Sebastes mentella) have contributed to the increase in abundance and biomass since 2013. The 2011 cohort, which is the most abundant, now has a modal size of 23 cm . These redfish are distributed throughout the channels of the northern Gulf of St. Lawrence (Figures 50 to 52).

## Invertebrates

The three most abundant shrimp species in the deep waters of the northern Gulf of St. Lawrence, namely northern shrimp (Pandalus borealis), striped pink shrimp (Pandalus montagui) and pink glass shrimp (Pasiphaea multidentata), have been declining for several years (Figure 68).
The abundance and biomass of the northern shrimp (Pandalus borealis) has declined significantly since 2003 to reach the lowest values in the historical series since 2017 (Figures 53 to 55).
Northern shortfin squid (IIlex illecebrosus), a seasonal pelagic species from the south, has been present in over $50 \%$ of the tows since 2017 in all areas except the estuary and Strait of Belle Isle. This strong squid presence had not been observed for several years (Figures 59 to 61).

For the second year in a row, a lobster (Homarus americanus) was caught in the study area at a depth of over 300 m between the northern Gaspé Peninsula and Anticosti Island. No lobster was caught during this survey prior to 2019 (Annex 2).
Four species of sea pens were present in the northern Gulf of St. Lawrence. The larger sea pens (Anthoptilum grandiflorum, Halipteris finmarchica, Pennatula grandis) are distributed in the deeper areas of the Laurentian Channel, while the spiny sea pen (Pennatula aculeata) had a more widespread distribution within the survey (Figures 59 to 62).

## PHYSICAL OCEANOGRAPHIC CONDITIONS

A preliminary analysis of water temperature data collected in 2020 (Figures 69 and 70) shows that conditions have warmed at 150 m and deeper, reaching new records since 1915 at 200,

250 (not shown) and 300 m (note that these annual record may change with the addition of data sampled during the fall). Compared to conditions observed in August 2019, waters at 200 and 300 m have warmed by about $0.2^{\circ} \mathrm{C}$ and by 0.3 and $0.4^{\circ} \mathrm{C}$ at 250 and 150 m where inter-annual variability is higher. The August cold intermediate layer (CIL) minimum temperature was much warmer in 2020 than in 2019 except in the Estuary where it remained stable. Surface waters were also much warmer than normal, by $1.5^{\circ} \mathrm{C}$, in July-August.

Air temperatures over the Gulf were below normal in April 2020, near normal in May and July and above-normal in June and August. This led to above normal average surface water temperatures for the period of May-August (+1.0 standard deviations [SD] relative to the 19822010 climatology and $+0.8^{\circ} \mathrm{C}$ ) as well as for July-August ( $+2.0 \mathrm{SD} ;+1.5^{\circ} \mathrm{C}$ ).

At the end of winter 2020, the volume of water in the surface mixed layer with temperatures lower than $-1^{\circ} \mathrm{C}$ was near the climatological mean, forecasting a warming of the summer Cold Intermediate Layer compared with 2019 conditions. Its average minimum temperature of $-0.1^{\circ} \mathrm{C}$, estimated for 2019 using only data from the August survey, was $0.3^{\circ} \mathrm{C}$ warmer than 2019 conditions, and was above-normal (+0.7 SD; Figure 70). The regional exception was the Estuary, where the CIL minimum temperature volume was similar to 2019 conditions ( $0.4{ }^{\circ} \mathrm{C}$; +0.3 SD; Figure 69) and of slightly larger volume.

Beneath the cold intermediate water layer, the estuarine flow that carries deep water to the channel heads has carried the increasingly warm waters that had been transitioning through Cabot Strait, central Gulf and Esquiman Channel for the past several years further upstream. Consequently, deep temperatures in August have increased since 2019 below 150 m almost everywhere (Figure 69). Taking into consideration all the data recorded in different months of the year, the four regions along the deep Laurentian Channel, meaning the Estuary, northwestern Gulf, Central Gulf and Cabot Strait, are all experiencing record temperatures at $300 \mathrm{~m}\left(5.9^{\circ} \mathrm{C}, 6.3^{\circ} \mathrm{C}, 6.9^{\circ} \mathrm{C}, 7.2^{\circ} \mathrm{C}\right)$. The annual mean has thus far exceeded $7^{\circ} \mathrm{C}$ in Cabot Strait for the second consecutive year. The Gulf-wide average temperature at 300 m has reached a record level since 1915 of $6.75^{\circ} \mathrm{C}$, an increase of $0.24^{\circ} \mathrm{C}$ since 2019 (Figure 70).

## ACKNOWLEDGEMENTS

We would like to thank both crews of the CCGS Teleost and wish to highlight the excellent work of the 2020 scientific team. The science team consisted of Hugo Bourdages, Nicolas Coulombe, Laurie Isabel, Jean-François Lussier, Marie-Claude Marquis, Jordan Ouellette-Plante, Eric Parent, Pierre-Marc Scallon-Chouinard et Caroline Senay. We also thank Denis Bernier for his support for the development of data entry tools and data management.
Finally, we would like to thank Charley Cyr for reviewing this document.

## Water temperatures in the Gulf

August/août 2020

Figure 69. Mean temperature profiles observed in each region of the Gulf during August 2020. The shaded area represents the 1981-2010 climatological monthly mean $\pm 0.5$ SD for August. Mean profiles for August and September 2019 are also shown for comparison. The violet outline on the map shows the area over which sea surface temperature is averaged for figure 70.

Water temperatures in the Gulf

Figure 70. Water temperatures in the Gulf. Sea-surface temperature averaged over the Estuary and the northern Gulf (see violet outline on map of figure 69) for July-August and May-August (1982-2020) (red lines). Layer-averaged temperature for the Gulf of St. Lawrence at 150, 200 and 300 m (green lines). Cold intermediate layer minimum temperature index in the Gulf of St. Lawrence adjusted to July 15, with 2020 value estimated only from August survey data (blue line).
