## SUMMARY

> For 2023 fishery management purposes, the Area 23 Roundtable has agreed to begin fisheries in the "Moderate" zone (500000-700000 adult return) for early season harvest management. Henderson Lake Sockeye remain a constraining stock in the "Low" zone.
> There is uncertainty among the 2023 forecast models. Predictions (Table 3) vary between 145000 (Sea Surface Temperature), 276000 (Coho Leading Indicator model), 465000 (multivariate model), and 723000 (sibling model). Forecast models for the 2023 aggregate Somass Sockeye return are described in Appendix A.
> All forecast models suggest Sproat Lake Sockeye will comprise the majority of the 2023 run. In 2019 and 2020 (broods returning as age 4 and 3 fish, respectively in 2023), escapements of Great Central Lake Sockeye were abnormally low (Figure 5). In addition, the estimated juvenile Sockeye abundances in Great Central Lake and Sproat Lake in the 2020 and 2021 sea-entry years were low compared to historic levels. Returns from the 2020 sea-entry year have thus far indicated a high marine survival rate, but the marine survival rate for the 2021 sea-entry year is more uncertain. Therefore, a precautionary management approach for early season fisheries is warranted until the total run size and stock composition can be more accurately determined. Inseason estimates of stock composition will be available during the second and third weeks of June; the first run size reforecast is expected 22 June 2023.
> The recommended management outlook for Henderson Sockeye is the "Low" zone for harvest management, corresponding to an expected return of 15000-25000 (Table 4). The key consideration influencing this outlook is a high marine survival rate in 2020, and moderate spawner abundances in the main contributing brood years, 2018-2019.

## BACKGROUND

Great Central Lake, Sproat Lake, and Henderson Lake are the three main Sockeye stocks returning to Barkley Sound (Area 23). The status of each stock is assessed as a separate Conservation Unit (CU) for implementation of Canada's Wild Salmon Policy. From 1980-2022, the median adult terminal returns (catch and escapement) of Great Central Lake, Sproat Lake, and Henderson Lake Sockeye are 312000, 241000 and 23000, respectively (Table 5). In the Somass Sockeye return, the historical median split between Great Central Lake and Sproat Lake abundance is $55 \%$ Great Central (inter-quartile range: 46$62 \%$ Great Central).
The pre-season biological forecasts for Somass Sockeye (outlined in this bulletin) inform a management forecast that guides June fishing plans (Table 8). The run size forecasts are revised weekly starting in the third week of June based on in-season indicators described later in this bulletin. The first in-season reforecast is anticipated no earlier than Thursday, 22 June 2023.

Data limitations preclude a statistical forecast for Henderson Sockeye. Instead, a management zone is set based on an outlook that considers spawner abundances and smolt abundances (when available) and indicators related to marine survival rates for the contributing brood years. This outlook informs the amount and timing of commercial gillnet openings in outer areas of Barkley Sound, which are more likely to intercept Henderson Sockeye (Table 9).

## 2023 SOMASS SOCKEYE BIOLOGICAL FORECASTS

Several indicators of varying accuracy are used to inform the pre-season Somass Sockeye biological forecasts: abundances of younger siblings from the same brood and smolt years as returning 2023 age classes, average sea surface temperatures and sea surface salinities recorded in outer Barkley Sound during the juvenile outmigration period (March-May), survival rates in Coho from the same brood year that return as adults one year earlier, and estimates of winter smolt abundances in Great Central and

Sproat Lakes. The predicted Somass aggregate return is further broken down into age- and stock-specific forecasts in Table 3.

Model forecasts for the 2023 aggregate Somass Sockeye return are described in detail in Appendix A and summarized here:

- The Multivariate forecast (Table 3, Figure 1) predicts a total return to the Somass river of 465000 (75\% prediction interval: 170000-1281000) adult Sockeye. The predicted returns to Great Central and Sproat Lakes are 170000 and 295000 adult Sockeye, respectively (36\% GCL).
- The Sibling forecast (Table 3) predicts a total return to the Somass river of 723000 adult Sockeye. The predicted returns to Great Central and Sproat Lakes are 307000 and 416000 adult Sockeye, respectively ( $42 \% \mathrm{GCL}$ ). The majority of adults predicted to return to GCL are age 42 , whereas the strength of the SPL return is predicted to come as 5 year-olds (Table 3).
- The sea-surface-temperature-based SStM forecast (Table 3) predicts a total return to the Somass river of 145000 adult Sockeye. The predicted returns to Great Central and Sproat Lakes are 67000 and 76000 adult Sockeye, respectively ( $47 \%$ GCL). Spring marine temperatures at Amphitrite Point were above average in 2020 and close to average in 2021, which results in a "low" survival scenario (2.5\%) for returning 5-year-olds and a "high" survival scenario (5\%) for returning 4-year-olds. Indications from the 2020-2021 sea-entry years suggest marine survivals are likely average to high for these cohorts (Figure 6). However, smolt abundances were low in both Great Central and Sproat Lakes through 2020-2021 (Figure 4).
- The Coho Leading Indicator (CLI) model predicts a total return to the Somass river of 276000 adult Sockeye. The predicted returns to Great Central and Sproat Lakes are 62000 and 214000 adult Sockeye, respectively ( $22 \% \mathrm{GCL}$ ). The CLI model accounts for spawner abundances in the contributing brood years, as well as the survival rate of Coho from the contributing sea-entry years. Coho survival rates were slightly above the 6\% average in 2020 (6.9\%) and 2021 (7.4\%).

## 2023 SOMASS SOCKEYE MANAGEMENT FORECAST

For fishery management purposes, the Area 23 Roundtable has agreed to manage to a forecast in the "Moderate" zone (see Table 8) corresponding to an expected return of 500000-700000 adult Sockeye.
Based on the projected return, a precautionary approach to fisheries management will be required until in-season information can inform run size estimates. In-season indicators that will be applied to inform management in 2023:

- Stock compositions from samples collected by the test fishery in June will be used as an indicator of the relative proportions of Great Central and Sproat Lake at the end of the run.
- Area D gillnet catch in Area 23 in the second and third weeks of June will be used as an indicator of the final Somass Sockeye adult return.
- The total cumulative accounting (escapement, catch, Alberni Inlet abundance estimate, and lower river abundance estimate) and estimated run timing will be used to predict the final Somass Sockeye adult return.
- Scale samples collected from the test boat, fisheries, and escapement at the fishways will inform the predicted age composition of the return.
- River temperatures and inlet conditions will inform holding patterns and migration conditions, which affect escapement timing, pre-spawn natural mortality, and susceptibility to fisheries.

## 2023 HENDERSON SOCKEYE OUTLOOK

The recommended management outlook for Henderson Sockeye is the "Low" zone for harvest management, corresponding to an expected return of 15000-25000 Sockeye (Table 4). Spawner abundances in the main contributing brood years were near the historical median of 13000 (12000

Sockeye in 2018, 13500 Sockeye in 2019; Table 4). Based on positive ocean indicators and data from incomplete brood years, marine survivals are expected to be high. Therefore, expectations are for a nearaverage Henderson sockeye return in 2023.

## APPENDIX A. FORECAST METHODOLOGY

## Statistical forecast models

Four models have historically been used to forecast Sockeye returns to Great Central and Sproat Lakes: the Survival Stanza Method (SStM), Surface Salinity Method (SSM), Salmonid Enhancement Program Biostandard Method (SEPB), and Coho Leading Indicator Method (CLI; Hyatt et al. 2003). More recently, a sibling regression model has been developed that uses the relationships between the returns of Sockeye at earlier ages to predict future returns of their older siblings (i.e. predicts age 4, 5, and 6 returns based on the abundance of earlier returning age 3, 4, and 5 fish from matching brood years; Peterman 1982, DFO 2012). In 2021, a multivariate multiple regression model was developed that integrates data from younger sibling abundances, smolt abundances, and sea-entry conditions. The multivariate regression model considers not only the individual effects of each predictor, but also their interactions (e.g. smolt abundance is likely predictive of adult returns only when sea-entry conditions are favorable).

The SStM and SSM use annual estimates of the numbers of smolts from Great Central and Sproat Lakes and predictors of early marine survival (marine temperature and salinity measured off Amphitrite Point, Ucluelet, respectively) to estimate returns (Hyatt et al. 2003).
The CLI model is based on the observation that marine survivorships for both juvenile Sockeye and Coho migrating through Barkley Sound and up the West Coast of Vancouver Island often covary because both species face similar physical and biological conditions at sea-entry in a given year (Hyatt et al. 2003). Because Coho return one year earlier than most Sockeye, Coho survival values observed in one year can be used to predict survival of Sockeye returning the following year.

In general, the Sibling and SStM forecasts have provided the most accurate forecasts over the long term, with mean absolute percentage errors (MAPE) of $39 \%$ and $62 \%$, respectively (Figure 7). Over the past 5 years, the Sibling and SSM models have performed the best (MAPEs of $41 \%$ and $80 \%$ respectively), while the SStM and CLI models have performed poorly (MAPEs of $90 \%$, 183\%, respectively; Figure 7). The Multivariate model appears to improve on the Sibling model, with a retrospective MAPE of $33 \%$ (Figure 8). The multiple regression analysis applied by the Multivariate model suggests that much of the variation in survival rates ascribed to sea-entry conditions in the smolt-based models is captured in the returning sibling abundances.
The forecasts generated from all methods are evaluated based on their relative accuracy at predicting past returns along with other relevant information (e.g. marine environmental conditions or observations). A heuristic management forecast for the Somass aggregate return is produced to guide early season fisheries. This forecast sets pre-season expectations and guides early-season harvest planning.

## 2022 forecast performance

The pre-season management forecast was in the "Low" zone with a predicted return of approximately 400000 adult Somass Sockeye (Table 2).
The observed return of approximately 880000 adult Somass Sockeye was in the $67^{\text {th }}$ percentile of all runs recorded since 1977 (Table 1, Table 5, Figure 2). Fish from the 2016-2019 brood years returned in 2022, with the majority contributed from 2017 and 2018. The proportion of age 42 fish ( $61 \%$ ) was well above the sibling model prediction (13\%), but similar to predictions from the Multivariate, CLI, and SStM models ( $68 \%, 54 \%$, and $53 \%$, respectively). The 2022 return included above average jack (ages $3_{2}$ and $4_{3}$ ) returns to both Sproat Lake and Great Central Lake.
The proportion of Great Central Lake in the total return (34\%) was lower than expected pre-season (41\%; average of the 4 forecast models employed). The returns from the 2017 brood year appear to be weighted toward Great Central Lake ( $72 \%$ Great Central in the 2017 brood returns) but returns from the 2018 brood year are heavily dominated by Sproat Lake ( $90 \%$ Sproat in the 2018 brood returns; Table 6).

All models under-predicted the 2022 return (Table 2). The prediction from the sibling model was closest to the observed return (absolute percentage error: $45 \%$ ). However, the sibling model also deviated most from the GCL/Sproat split in the final 2022 return, with a $54 \%$ predicted GCL. All models correctly
predicted that the age 42 return to Sproat Lake would be the dominant component in the 2022 return. In the 2019 sea-entry year (age 52 and $6_{3}$ Sockeye returning in 2022), the smolt abundance in GCL was average, and in 2020 GCL smolt abundance was very low; these abundances translated to a strong adult return to GCL in 2021. This combination of average and low smolt abundances in GCL led the smoltbased forecast models (CLI, SStM) to under-predict the return considerably; preliminary data from the 2020 sea-entry year suggest a high survival rate of $11.7 \%$ (Figure 6), well above the $6.9 \%$ and $5.0 \%$ applied in the CLI and SStM, respectively.
The return of approximately 26000 Henderson Lake Sockeye in 2022 exceeded the 10-year median of $c$. 16000 (Table 1, Table 5, Figure 3). The pre-season outlook was for a management zone of "very low" (i.e., < 15,000 Sockeye). Pre-season expectations were based on the relatively low spawner abundance observed in the 2018 brood year, and an expectation for low marine survival rates to be experienced by the 2019 and 2020 sea-entry years. However, returns thus far from the 2020 sea-entry year indicate a high marine survival rate (see above).

## Sources of uncertainty

The mean absolute percentage errors (MAPEs) for the five forecast models used to predict Somass Sockeye range from about 40-208\%. Retrospective analysis suggests the Multivariate model is the best performing forecast (Table 3; Figure 7). On average, the observed return is about $40 \%$ higher or lower than the return predicted by the Multivariate model. Factors that contribute to forecast uncertainty include, but are not limited to: model structure, assumptions about the relationships between returns and the predictor variables, and uncertainty in the source data (e.g. smolt abundances, age compositions in historical returns).
For the Henderson Sockeye outlook, there is considerable uncertainty due to lower quality assessment data relative to the Somass stocks. There are less complete age data, relatively high uncertainty in the estimates of spawner abundance, and uncertainty in catch estimates. Catch estimates are particularly uncertain in recent years when the abundance of Henderson Sockeye is low relative to the Somass stocks. Under these circumstances, the probability of detection of Henderson Sockeye in catch samples is lower and therefore catch of Henderson Sockeye may be underestimated.
The relationships between available ocean indicators and survival rates in Area 23 Sockeye are uncertain. While there are weak correlations between spring sea surface temperatures and salinities measured at Amphitrite Point and Somass Sockeye survival, some years with seemingly excellent ocean conditions (e.g. 2002) have not yielded high survivorship. Investigative analyses carried out in 2023 suggest there is likely a better relationship between offshore sea surface temperatures (from ECCC buoy c46132 "South Brooks") from February-April in sea-entry years compared to the nearshore temperatures recorded at the Amphitrite Point lightstation. However, 2019-2020 data are missing from the South Brooks historical record, so these data could not be used to predict 2023 returns. Smolt estimates for the 2018-2021 sea-entry years were derived from a revamped acoustic-trawl survey program and are considered to have better accuracy compared to previous years in the historical record.

Table 6. Escapement, catch, and total return-at-age to date from brood years contributing to the 2023 Somass Sockeye return. Note.-data from each brood year span multiple return years; e.g. fish from the 2017 brood year returned as age 3 s in $2020,4 \mathrm{~s}$ in $2021,5 \mathrm{~s}$ in 2022 , and will return as age 6 s in 2023.

Table 7. Estimates of juvenile Sockeye abundance (millions) in Great Central, Sproat, and Henderson Lakes for smolt years 1980-2021. Most Sockeye returning in 2023 went to sea in 2020 and 2021. Note.Since 2014 in GCL and 2015 in Sproat, age compositions are based on historical averages rather than observed scale ages in smolt biosamples (indicated with grey and italicized numbers in the table below).

| Sea-entry year | Great Central Lake |  |  | Sproat Lake |  |  | Henderson Lake |

Table 8. Excerpt from the management plan: Standardized Area 23 Sockeye Fishing Regime for early-season (June) fisheries. Typically, commercial seine fisheries are not planned until late June. However, all fisheries may be adjusted depending on in-season assessment results.

| MANAGEMENT | FORECAST RUN SIZE | MAANULTH FIRST NATIONS | RECREATIONAL | $\begin{gathered} \text { TSUMASS } \\ \text { ECONOMIC } \\ \text { OPPORTUNITY } \end{gathered}$ | COMMERCIAL SEINE* | COMMERCIAL GILLNET |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 1-Critical | Less than $\mathbf{2 0 0 , 0 0 0}$ | no harvest | no harvest | no harvest | no harvest | no harvest |
| 2 - Very Low | 200,000 to 350,000 | Open, fishing to target through limited effort (designated $\mathrm{g} / \mathrm{h}$ vessels) | 2 fish/day <br> + Area restrictions <br> + Late opening | Community/elder seine 1 day/week g/n | no harvest | 1 day/week starting 64 (1 day total) |
| 3 - Low | 350,000 to 500,000 | Open, fishing to target through limited effort (designated $\mathrm{g} / \mathrm{n}$ vessels) | 2 fish/day <br> + Area restrictions | Community/elder seine 2 days/week g/n | seine fishing to target | 1 day/week starting 63 (2 days total) |
| 4 - Moderate | 500,000 to 700,000 | Open, fishing to target through limited effort (designated $\mathrm{g} / \mathrm{h}$ vessels) | 4 fish/day (time-area closures if required) | Community/elder seine 3 days/week g/n | seine fishing to target | 1 day/week starting 62 <br> (3 days total) |
| 5 - High | $\begin{gathered} 700,000 \text { to } \\ 1,000,000 \end{gathered}$ | Open, fishing to target through limited effort (designated $\mathrm{g} / \mathrm{n}$ vessels) | 4 fish/day (time-area closures if required) | Community/elder seine 4 days/week g/n | seine fishing to target | 1 day/week starting 62 <br> (3 days total) |
| 6 - Abundant | 1,000,000 + | Open, fishing to target through limited effort (designated $\mathrm{g} / \mathrm{h}$ vessels) | 4 fish/day | Community/elder seine 5 days/week g/n | seine fishing to target | 1 day/week starting 61 <br> (4 days total) |

Table 9. Excerpt from the management plan: General guidelines for allowable fishery openings in the outside area (Barkley Sound) for Area D Gillnet associated with the Henderson Sockeye outlook. These guidelines are designed to reduce the exploitation rate of Henderson Sockeye as the expected abundance declines. Additional time and area measures may be applied in-season depending on environmental conditions and observed migration behavior.

| MANAGEMENTZONE | HENDERSON RUN SIZE | REFERENCEPOINT | TAC ${ }^{1}$ | HARVEST REGIME ${ }^{2}$ |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  |  | Outside Area Openings | Outside Area Closure | Maximum <br> Harvest Rate |
| 1 - Very Low | UP to 15,000 |  | - | June only | July 1 | 9\% |
| 2 - Low | $\begin{gathered} 15,000 \text { to } \\ 25,000 \end{gathered}$ | low end | 1,317 | June + up to 1 day July | July 8 | 9\% |
|  |  | high end | 2,926 |  |  | 12\% |
| 3 - Moderate | $\begin{gathered} 25,000 \text { to } \\ 45,000 \end{gathered}$ | low end | 2,926 | June + up to 2 days July (1 per week) | July 15 | 12\% |
|  |  | high end | 7,900 |  |  | 18\% |
| 4-High | $\begin{gathered} 45,000 \text { to } \\ 60,000 \end{gathered}$ | low end | 7,900 | June + <br> up to 3 days July (up to 2 per week) | July 15 | 18\% |
|  |  | high end | 14,045 |  |  | 23\% |
| 5 - Abundant | $\begin{gathered} \text { 60,000 to } \\ \text { 150,000 } \end{gathered}$ | low end | 14,045 | June + up to 4 days July (2 per week) | July 15 | 23\% |
|  |  | high end | 43,890 |  |  | 29\% |

1. Not including TAC associated with Maanulth Treaty or Maanulth Harvest Agreement.
2. The harvest regime may be adjusted based on the results of catch composition analysis.

Figure 1. Multivariate model predictions and observed returns by Gilbert-Rich age (columns) and lake (rows; GCL = Great Central Lake, SPR = Sproat Lake). Black lines and the shaded areas around them show the mean predictions and $75 \%$ prediction interval, respectively. Point forecasts and prediction intervals for 2023 are overlaid on each panel as dots with whiskers. The 6-point SST-salinity index was developed to reflect the relative hospitability of ocean conditions for juvenile Somass Sockeye during their Spring outmigration period; higher values reflect lower sea surface temperatures and higher salinities.

Figure 2. Estimated adult returns of Somass (Great Central and Sproat Lake) Sockeye, 1984-2022.

Figure 3. Estimated adult returns of Henderson Lake Sockeye, 1984-2022.

Figure 4. Estimated Sockeye "pre-smolt" juvenile abundances for Great Central, Sproat, and Henderson Lakes by sea-entry year. Most adult Sockeye returning in 2023 are associated with the production from the 2019 and 2020 sea-entry years.

Figure 5. Time series of adult escapements to the Somass River. The black dashed line shows the historical median \% GCL in the total return (56\%).

Figure 6. Time series of the marine survival rate index for Somass Sockeye stocks. Red dots and lines indicate the sea-entry years associated with the 2023 return; most adult Sockeye returning in 2023 went to sea in 2020 ( $5_{2}$ and $6_{3}$ Sockeye) and 2021 ( 42 and $5_{3}$ Sockeye). Although the survival rate index for those years is incomplete (not all fish that went to sea in those years have returned as adults), observed survivorships for the past 4 sea-entry years appear below average.

Figure 7. Time series of differences between predictions from the various forecast models and the observed Somass Sockeye returns.

Figure 8. Retrospective analysis of multivariate forecast performance. The observed returns of Somass Sockeye adults are plotted as black dots connected by the black line. The red line shows the multivariate forecast model predictions for each year, and the red shaded area shows its $75 \%$ prediction interval.
