Status of Atlantic Salmon (*Salmo salar* L.) Stocks of the
Newfoundland Region, 1984

by

¹ This series documents the scientific basis for fisheries management advice in Atlantic Canada. As such, it addresses the issues of the day in the time frames required and the Research Documents it contains are not intended as definitive statements on the subjects addressed but rather as progress reports on ongoing investigations.

Research Documents are produced in the official language in which they are provided to the Secretariat by the author.

¹ Cette série documente les bases scientifiques des conseils de gestion des pêches sur la côte atlantique du Canada. Comme telle, elle couvre les problèmes actuels selon les échéanciers voulus et les Documents de recherche qu'elle contient ne doivent pas être considérés comme des énoncés finals sur les sujets traités mais plutôt comme des rapports d'étape sur les études en cours.

Les Documents de recherche sont publiés dans la langue officielle utilisée par les auteurs dans le manuscrit envoyé au secrétariat.

Abstract

The commercial harvest of Atlantic salmon for the Newfoundland Region in 1984 showed a decline from 1983 (one of the worst years on record). Catches in the recreational fishery on the other hand were average, as were fishway counts, suggesting that river escapements were average. Catches were most likely influenced by the reduction in effort resulting from restrictions implemented under the 1984 Management Plan, namely a shortened season and a licence buy-back program. Also, for fishermen taking part in the commercial fishery, there are indications from logbook surveys that for a given Statistical Area, low catches of salmon, coupled with a corresponding greater emphasis placed on the exploitation of other commercial species and/or the presence of icebergs, resulted in only a portion of the total licenced gear being fished. Reduced effort most likely allowed salmon to escape the commercial fishery in numbers sufficient to maintain river escapements at average levels. This is suggestive of an overall low abundance of salmon in 1984.

Résumé

La pêche commerciale du saumon de l'Atlantique dans la région de Terre-Neuve en 1984 a présenté une diminution par rapport à celle de 1983 (une des pires années enregistrées). D'autres part, le nombre de prises en pêche récréative a été moyen, tout comme les dénombremens effectués, ce qui porte à croire que la nombre d'échappements dans les rivières a été moyen. Il semble que la principale cause de la diminution des prises ait été la réduction des efforts de pêche résultant des mesures du plan de gestion de 1984, notamment une saison de pêche écourtée et un programme de rachat des permis. De plus, dans le cas de la pêche commerciale, les relevés des carnets de bord pour une zone statistique donnée indiquent que les faibles prises de saumons, combinées à une exploitation accrue d'autres espèces commerciales, et/ou la présence d'icebergs se sont traduites par l'utilisation partielle des agrès de pêche autorisé. La réduction des efforts explique sans doute pourquoi les saumons ont pu échapper à la pêche commerciale en nombres assez élevés pour maintenir un niveau moyen d'échappements dans les rivières. Ces conditions semblent expliquer la faible abondance globale du saumon en 1984.

Introduction

This paper presents the status of Atlantic salmon stocks in the insular Newfoundland (Fig. 1) and Labrador (Fig. 2) portions of the Newfoundland Region in 1984. Catch and effort statistics for the commercial and recreational fisheries and fishway counts (insular Newfoundland) are examined in relation to historical data and the 1984 Management Plan.

Under the 1984 Management Plan, the start of the Newfoundland and Labrador commercial fishery was delayed until June 5 (compared to May 18 for 1981-83 and May 15 prior to 1981). Statistical Area J2 was completely closed and a compulsory licence buy-back program put into effect. A voluntary buy-back program involving both full-time and part-time fishermen went into effect for the remaining Statistical Areas. These restrictions were implemented as a means of reducing the interception of mainland-origin salmon as well as salmon destined to return to depleted rivers on the southwest coast of Newfoundland. An estimated 25% of the total number of large (multi-sea-winter) salmon taken in the Newfoundland and Labrador commercial fishery are of mainland origin (Pippy 1982). With respect to the recreational fishery, a catch-and-release policy pertaining to large salmon was adopted for insular Newfoundland; regulations governing grilse (one-sea-winter salmon) remained unchanged. Labrador was exempt from the catch-and-release regulation.

Methods

The 1984 catch and effort data were added to that previously presented by Moores et al. (1978), Moores and Tucker (1979, 1980), Ash and Tucker (1984), Moores and Ash (1984), and Ash and O'Connell (unpublished) for the recreational fishery and to that found in May and Lear (1971), Waldron (1974), Reddin and Waldron (1976), Reddin and Day (1980), Reddin and Short (1981), Short and Reddin (1981a, 1981b), Ash (1984), Moores et al. (1984), and Ash and O'Connell (unpublished) for the commercial fishery. Effort in the commercial fishery was presented as the numbers of gear units (50 fathoms of gill net or salmon trap) licenced to prosecute the fishery. Recreational fishing effort was presented as rod days (defined as any day or part thereof on which an angler fishes) and represents actual effort reported by DFO personnel. It contains an estimation of catch and effort during staff days off.

The calculation of mean weights of small (one-sea-winter) and large (multi-sea-winter) salmon as well as estimated numbers of fish in each category followed procedures outlined in Ash (1984).

Means and 95% confidence intervals for ratio variables were calculated according to Cochran (1977). Correlation analysis of commercial catch data by Statistical Area was done with Statistical Analysis Systems (1982) programs.

Results

Commercial fishery

The commercial catch for the entire Newfoundland Region (insular Newfoundland and Labrador combined) in 1984 is summarized in Table 1. Compared to 1983 (one of the worst years on record), landings in terms of weight of one-sea-winter (1SW) and multi-sea-winter (MSW) salmon decreased by 18.6 and 22.4% respectively; with respect to number of fish, the corresponding declines were 19.0 and 23.2% respectively. Compared to the 1969-83 mean, 1SW and MSW catches decreased by 40.3 and 55.2% respectively by weight and 40.3 and 52.8% respectively by number. For the island portion of the Newfoundland Region (Table 2), the catch of 1SW salmon decreased by 9.9% by weight and 9.4% by number from 1983, while for MSW salmon the decreases were 19.6% by weight and 18.9% by number; compared to the 1969-83 mean, 1SW and MSW catches decreased by 35.0 and 53.4% respectively by weight and 34.2 and 49.7% respectively by number. Catches for the Labrador portion of the Newfoundland Region in 1984 declined more strongly from 1983 than that presented above for insular Newfoundland. Catches of 1SW and MSW salmon declined by 44.0 and 25.5% respectively by weight and 48.2 and 28.2% by number from 1983; the declines from the 1969-83 mean were 56.8 and 57.2% for 1SW and MSW salmon respectively by weight and 60.0 and 56.2% by number.

An examination of insular Newfoundland on a Statistical Area basis reveals that catches of MSW salmon were below the lower limit of the 95% confidence interval of the 1969-83 mean in all cases (Tables 4 - 13). Catches of 1SW salmon on the other hand were within the 95% confidence interval for Statistical Areas B, C, F, G, and H (very close to the mean in most instances), but below the lower limit for the remaining Areas. For the Labrador portion of the Newfoundland Region, landings of MSW salmon were below the lower limit of the 95% confidence interval for Statistical Sections 51 - 53 (Tables 14 - 16); the same was true for 1SW catches in Sections 51 and 52, but not 53 where catches were within the confidence limits.

Recreational fishery

The catch of grilse in the 1984 recreational fishery for the entire Newfoundland Region (Table 17) increased by 11.0% over 1983. The 1984 catch was the same as the 1979-83 mean, but increased by 21.7% over the 1969-83 mean. For the island portion of the Newfoundland Region (Table 18), the grilse catch in 1984 increased by 14.3% over 1983; this catch represented an increase of 3.6 and 30.1% over the 1979-83 and 1969-83 means respectively. For the Labrador portion of the Newfoundland Region (Table 19), the grilse catch in 1984 decreased by 19.3% from 1983; this catch was also a decrease of 35.2 and 33.8% from the 1979-83 and 1969-83 means respectively.

The catch-and-release regulation under the 1984 Management Plan referred to above did not become official until August 8. Therefore, up to that time the release of large salmon was strictly voluntary. Released large salmon,

although counted as part of the bag limit, were not officially recorded as catch by Resource Management Division personnel. The value for large salmon for the island portion of the Newfoundland Region presented in Table 18 represents fish retained by anglers, i.e. not voluntarily released. Labrador was exempt from the catch and release regulation. The 1984 large salmon catch for Labrador increased by 6.0% over 1983, but was down by 27.6 and 23.4% respectively from the 1979-83 and 1969-83 means (Table 19).

On a Statistical Area basis for insular Newfoundland (Tables 20 - 29), the catch in 1984 (considering grilse only for reasons pointed out above) was higher than that recorded for 1983 for all Areas except A, E, and G. The difference for G was only slight, but for Areas A and E the decreases were substantial (39.5 and 30.9% respectively). Compared to the 1979-83 long-term mean, catch in 1984 was within the 95% confidence interval (close to or exceeding the mean in most cases) for all Areas except A and E where catch was below the lower limit. In terms of the 1969-83 mean, 1984 catch was within the 95% confidence interval in most cases, except for Areas G, H, and J1 where the upper limit was exceeded. For Statistical Sections 51 and 52 of Labrador (Tables 30 - 31), the catch of grilse and large salmon in 1984 was down substantially from 1983; the reverse was true for Section 53 (Table 32).

Effort for the entire Newfoundland Region in 1984 (Table 17) decreased only slightly from 1983 (3.1%). For insular Newfoundland (Table 18) there was a decrease of 3.07% compared with 3.32% for Labrador (Table 19). On a Statistical Area basis for insular Newfoundland (Tables 20 - 29), effort was below 1983 (ranging from 4.2% for J1 to 46.8% for A) for all Areas except B and C which recorded increases of 11.2 and 21.7% respectively. Effort for 1984 was generally within the 95% confidence intervals of the 1979-83 means and in most cases, above the upper limits of the 1969-83 means. For Statistical Sections 51 and 52 (Tables 30 - 31), effort for 1984 decreased (22.0 and 5.8% respectively) from that of 1983; Section 53 (Table 32) increased by 19.9%. Effort for 1984 was above or within the 95% confidence limits of both long-term means.

Catch per unit effort for the Newfoundland Region in total (Table 17) in 1984 increased by 13.8% over 1983. For the island alone (Table 18), there was an increase of 14.8%; for Labrador catch per unit effort dropped by 12.9% (Table 19). Comparing Statistical Areas for insular Newfoundland (Tables 20 - 29), catch per unit effort in 1984 increased over 1983 for Areas A, D, F, G, H, I, and J1 (range was 14.3% for A to 100% for F and H); Areas B, C, and D showed a decrease (5.7, 12.0, and 30.2% respectively). Compared to the long-term means, most Areas were within or above the 95% confidence limits. For Statistical Sections 51 and 52, catch per unit of effort in 1984 declined by 36.4% and 27.4% respectively from 1983, while for section 53, an increase of 23% was noted (Tables 30-32); values for 1984 were generally below the lower limits of the long-term means.

Fishway counts

Counts of grilse in 1984 increased over 1983 for all fishways except Indian River (Table 33). Compared to the 1979-83 mean, most showed an

increase, being most pronounced for Bishop's Falls and Great Rattling Brook. Large salmon increased over 1983 for all fishways except Indian River, Great Rattling Brook, and Middle Brook (Table 34). Compared to the 1979-83 mean, Indian River, Bishop's Falls, Great Rattling Brook, and Middle Brook decreased while the remainder showed an increase. It should be pointed out that the long-term means in some instances should be higher because of the inclusion of partial counts.

Discussion

Any conclusions regarding the status of Atlantic salmon stocks in 1984 relative to previous years have to take into account the possible confounding effects of the 1984 Management Plan. One question pertaining to the delayed opening of the commercial fishery is what proportion of fish originating in a given Statistical Area were intercepted in another Area? The results of smolt tagging studies conducted on Sand Hill River, Labrador (Section 52) in the early 1970s (Pratt et al. 1974), Exploits River (Section 07) in 1978, and North Harbour River, St. Mary's Bay (Section 28) during 1961-67 (Lear and Day 1977) are presented in Fig. 3 - 5, respectively. It is evident that the majority of both 1SW and MSW salmon recaptures occurred in the general region of the river of origin. Some 1SW recaptures may not have been grilse and instead were destined to become MSW salmon. This pertains mainly to distant recaptures; local recaptures were most likely grilse. Significant positive relationships resulting from a correlation analysis of commercial landings (1969-83) by Statistical Area (Table 35) are indicative of a tendency towards clumpings involving Areas in close geographical proximity for both 1SW and MSW salmon. While there is an overall indication that stocks are harvested mainly in the general vicinity of home waters, there is some evidence to suggest that the proportion of MSW salmon taken in more distant areas can vary annually as a result of distributional changes related to environmental conditions. An examination of tag returns for Sand Hill River (Fig. 3) reveals that in 1972, MSW salmon recaptures occurred considerably farther southward than that observed for 1971 and 1973. Likewise, the 4.0°C isotherm (surface) for the month of June (determined from British Meteorological Office (BMO) charts) extended much farther southward in 1972 than in 1971 and 1973. Also, there was a more southerly distribution of ice in 1972 (Fig. 6) than in 1971 (Fig. 7). From this, it is reasonable to conclude that ice conditions with attendant effects on water temperature in 1972 possibly resulted in MSW salmon striking in over an area much farther south than in 1971 and 1973. No such distributional change was noted for 1SW salmon. The Sand Hill River MSW recaptures along the northeast and east coasts of insular Newfoundland in 1972 occurred after June 5. An examination of the BMO chart for June 1984 showed the 4.0°C isotherm to be positioned in a similar manner to that observed for June 1972. Whether or not the same distribution of MSW salmon observed for 1972 also occurred in 1984 is unknown. The three MSW recaptures in Notre Dame Bay resulting from the Exploits River tagging study occurred prior to June 5; all other recaptures (both 1SW and MSW) were reported subsequent to June 5. The above tagging information establishes the fact that salmon originating in one Statistical Area are captured in another Area. Unfortunately, while there

are certain sources of environmental data available, without accompanying adequate smolt tagging information, any conclusions drawn as to the possible impacts of the delayed season in terms of such interceptions, remain purely speculative.

The overall low commercial catches of MSW salmon in 1984 reflect earlier predictions of low abundance by O'Connell et al. (1983) and Porter and Ritter (1984). For 1SW salmon on the other hand, O'Connell et al. (1983) predicted average abundance for all insular Newfoundland Region Statistical Areas except C, H, and J1; these predictions were based on average recreational catches in 1979 (assuming a 3+ modal smolt age) which were used as an index of spawning escapement (Chadwick 1982). All things being equal, if commercial catches are any indication of abundance, these predictions were obviously wrong in most cases; indeed, two of the three Areas where low abundance was predicted (C and H) recorded average catches in 1984. With respect to Labrador, predictions for 1SW salmon held true while for MSW salmon, results were ambiguous.

Catches of both 1SW and MSW salmon in 1984 were most likely affected by the reduction in effort resulting from the shortened season and the licence buy-back program. As well, for fishermen taking part in the fishery, there are indications that the amount of total licenced effort actually fished was low. A survey of commercial fishermen in Leading Tickles (Section 06) and Joe Batt's Arm (Section 08) in Notre Dame Bay in 1984 (O'Connell, unpublished) revealed that ice conditions (mainly the presence of icebergs) hampered the setting of gear for much of June, while in July lower effort was expended due to low catches of salmon (1SW and MSW) coupled with a greater emphasis placed on the exploitation of other species. Averaged over the period June 5 - early August, only 22% of the total licenced gear was fished in Leading Tickles (29 fishermen surveyed) and 19% in Joe Batt's Arm (31 fishermen surveyed). A survey of commercial fishermen in the Bay de Verde area of Conception Bay (Section 20) in 1984 showed the same conditions described above for Notre Dame Bay more or less prevailed here as well; overall, 30% of the total licenced gear was used (31 fishermen surveyed). In the Port de Grave area (Section 22), icebergs did not pose much of a problem with respect to setting gear (Port de Grave is located in the inner part of Conception Bay as opposed to the outer bay for Bay de Verde). However, scarcity of salmon from the beginning of the season onwards, along with greater effort directed towards exploitation of other species, resulted in only 22% of the total licenced gear being fished overall (30 fishermen surveyed). Similar observations were made for Conception Bay by O'Connell et al. (1984). In Labrador, the presence of pack ice hampered fishing for most of June and July in Sections 52 and 53. A regression of commercial landings in the Nain area on the surface area of shore-fast ice was negative and significant at the 5% level of confidence (Fig. 8); 1984 had the lowest landings and highest concentration of ice in terms of area. Landings most likely reflect low effort expenditure in relation to ice conditions and probably distribution patterns of salmon related to water temperature.

The recreational fishery in 1984 on the whole in insular Newfoundland was slightly better than in 1983 and compares quite favorably historically speaking. The angling season in insular Newfoundland in 1984 was characterized by high water temperatures and low water levels for a large part of the summer. This is demonstrated by temperature and water height data (Fig. 9) collected at

fishways and counting fence installations around the island (Fig. 10) in 1984. These conditions resulted in the closure of a large number of rivers for varying periods (most for nearly a month -- mid-July to mid-August) throughout the summer (Table 36). Had these conditions not prevailed, angling catches obviously would most likely have been higher. The recreational catch in Area A, as already pointed out, showed a sharp decline in 1984. This could be due in large part to the relative contribution of Main River (Sop's Arm) which can account for up to 60% of the total Area catch. Recreational catch for Main River in 1984 (Table 37) was below the exceptionally low level (relative to recent years) recorded in 1983.

Traditionally, on the north coast of the island, the commercial fishery commenced during the early part of June. On the south coast on the other hand, the fishery normally started at the opening of the season, i.e. mid-May. One would expect therefore the impact on river escapements, and hence recreational catch, of delaying the commercial fishery by two weeks to be felt mainly in more southern areas. It is not possible using recreational data on a Statistical Area basis to evaluate the possible contribution of fish released from the commercial fishery. With respect to large salmon, because of the catch and release regulation, the only way to assess escapements of this component in relation to the commercial fishery is by fishway counts; however, no firm conclusions can be drawn from these data. The fact that recreational catches and fishway counts were average in the face of overall low commercial catches was probably due to reduced fishing effort in the commercial fishery as a result of one or the other or all of the factors described above for a given Statistical Area. Reduced fishing effort resulted in the release of salmon from the commercial fishery in numbers sufficient to maintain river escapements at average levels. This is suggestive of an overall low abundance of salmon in 1984.

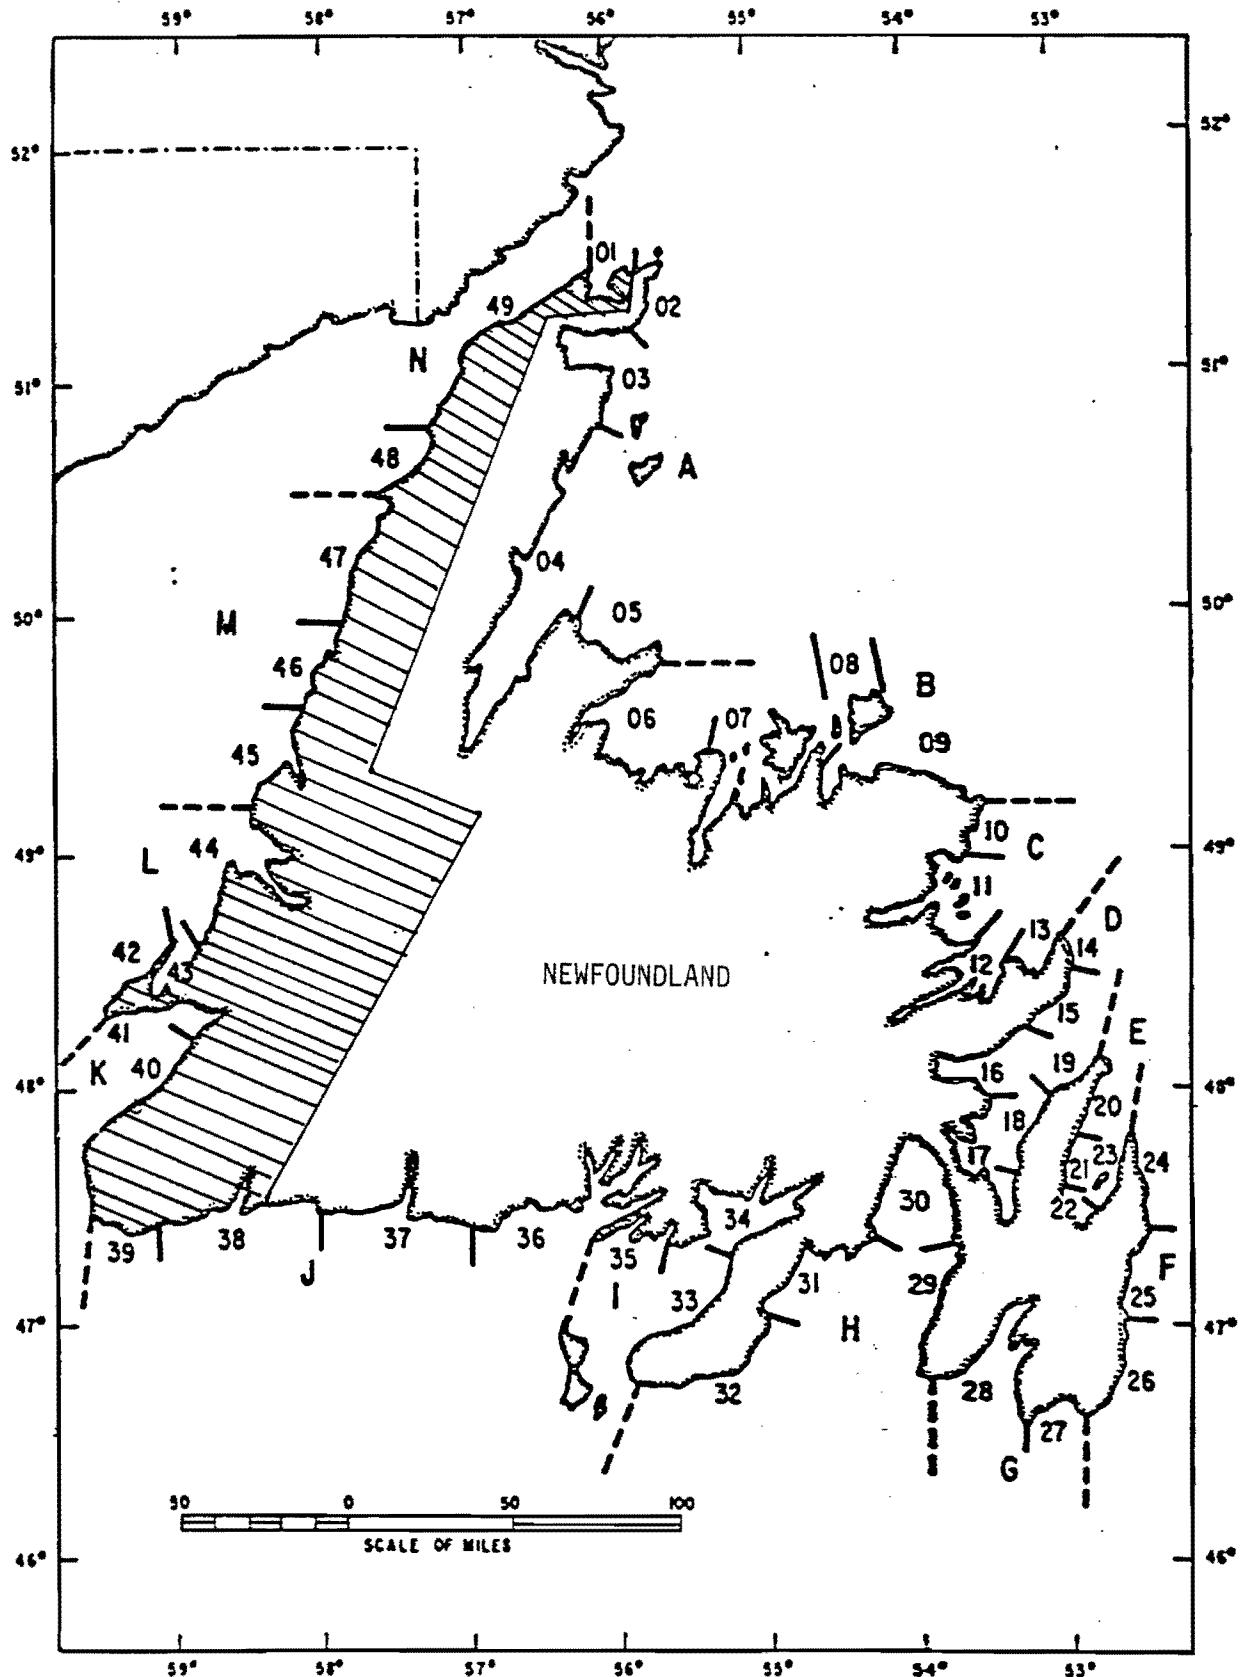

Fig. 1. Boundaries of Statistical Areas (alphabetical) and Statistical Sections (numerical) for insular Newfoundland. Cross-hatched portion denotes area belonging to the Gulf Region.

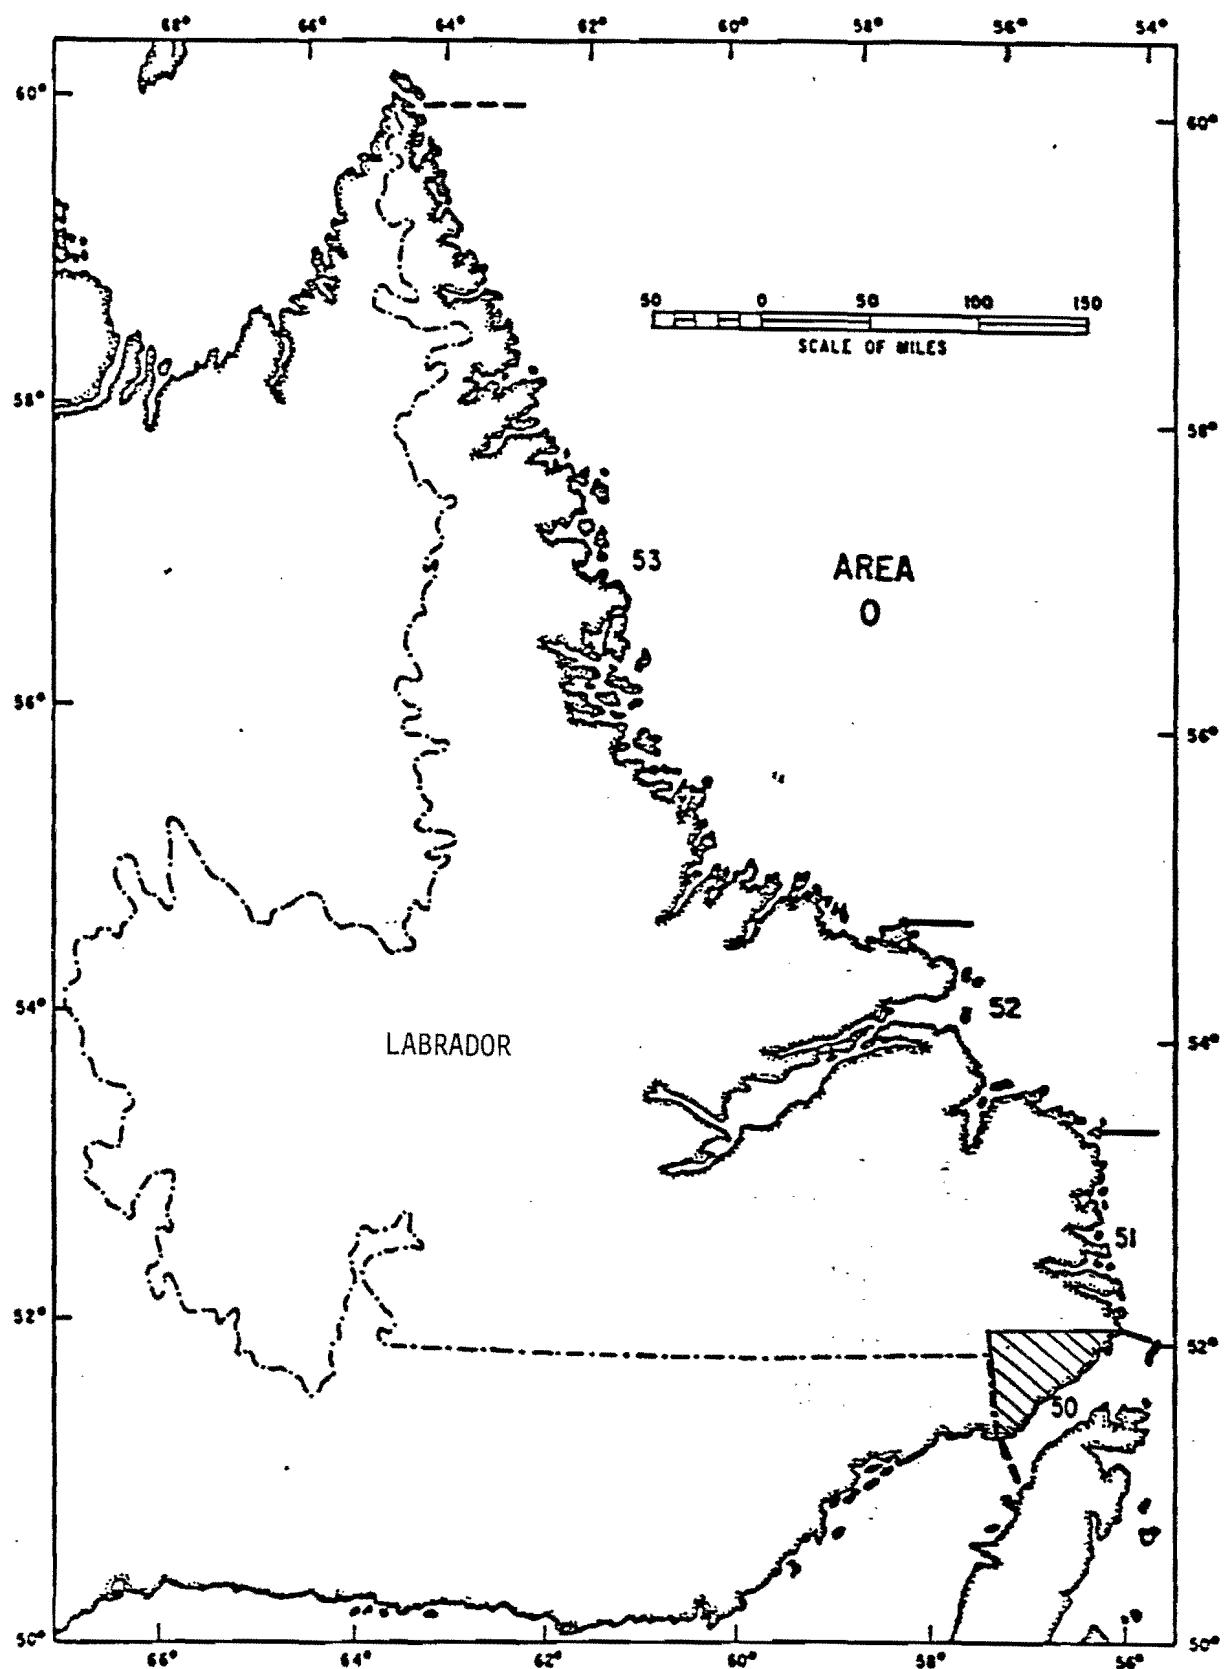

Fig. 2. Boundaries of Statistical Sections for Labrador (Statistical Area 0). Cross-hatched portion denotes area belonging to the Gulf Region.

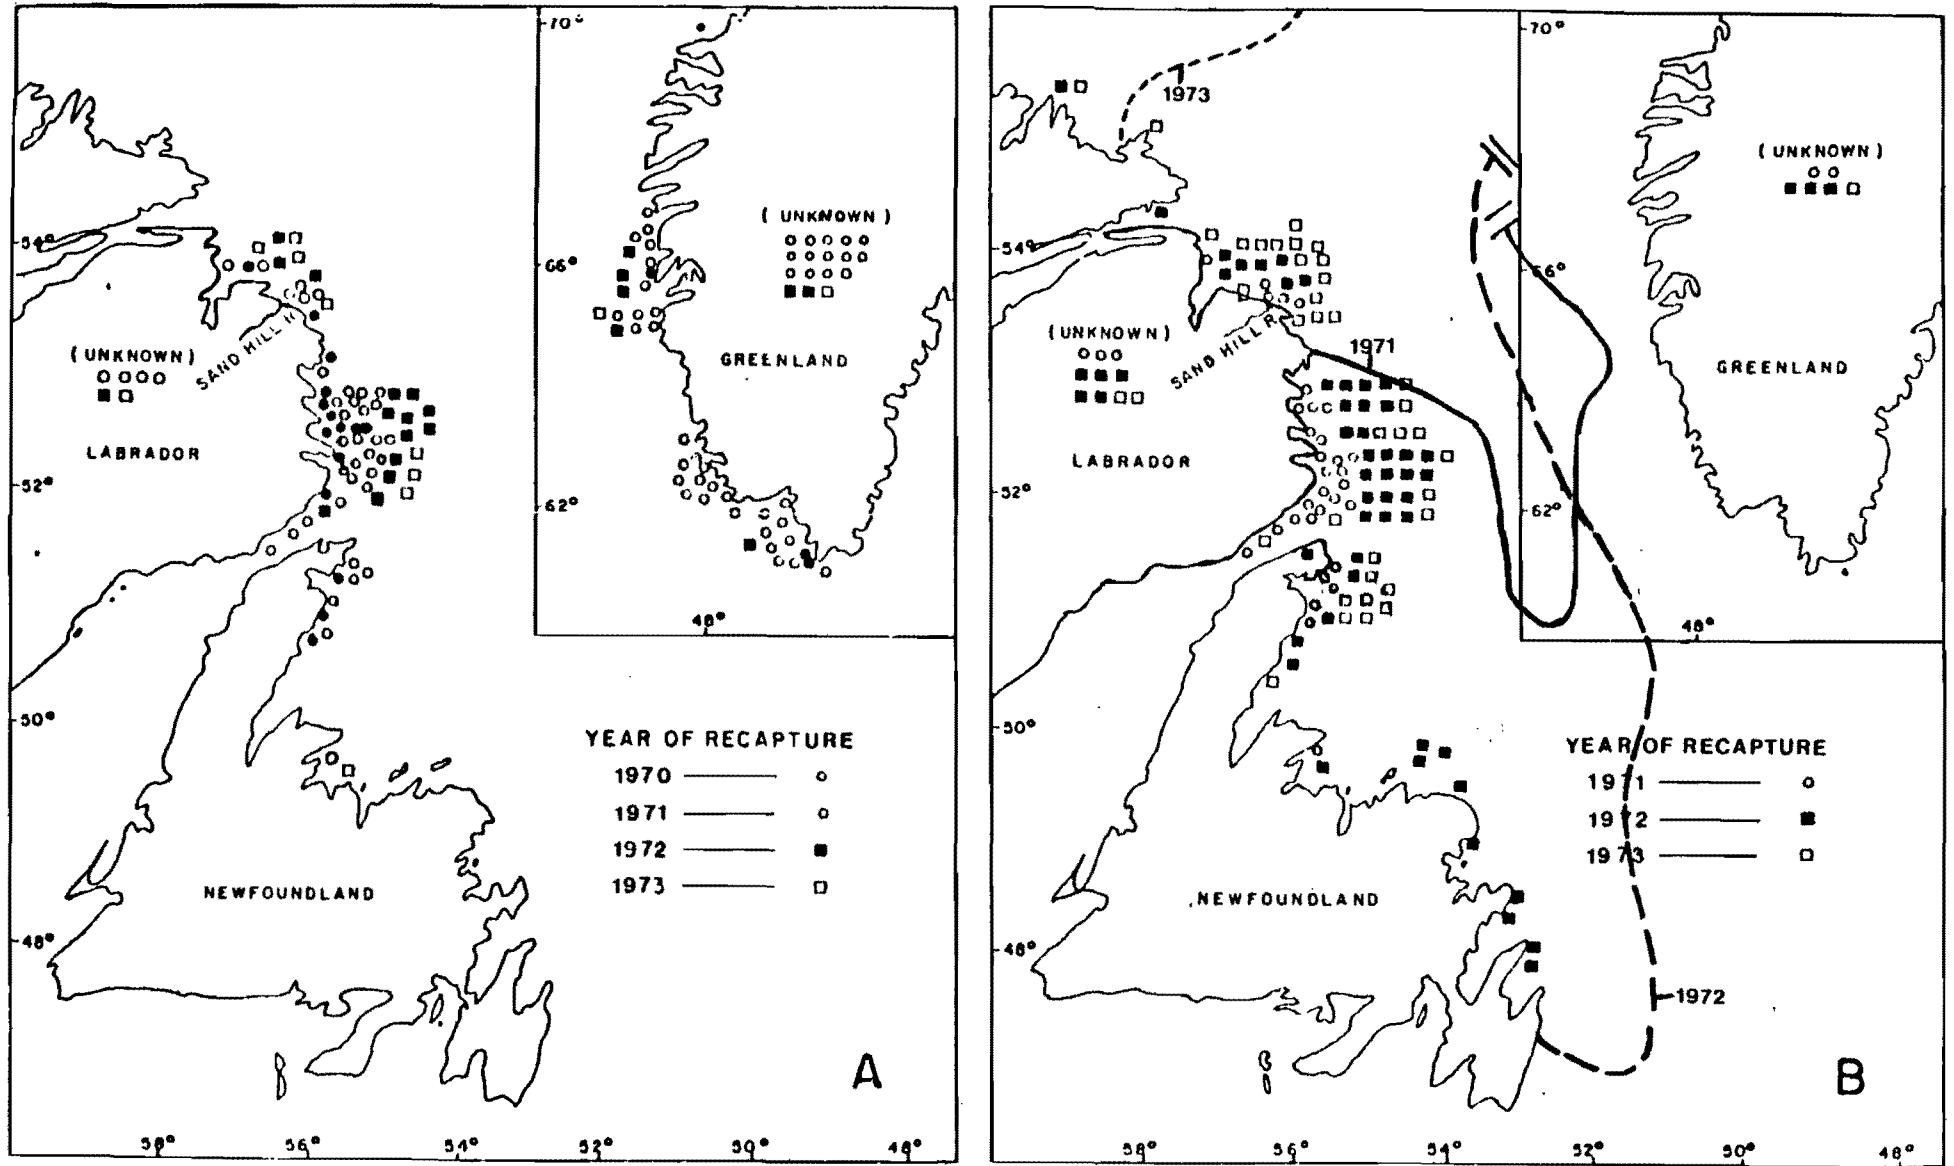

Fig. 3. Distribution of captured 1SW (Panel A) and MSW (Panel B) salmon that were tagged as smolts at the Sand Hill River counting fence, Labrador. From Pratt et al. (1974). Also shown are the approximate locations of the 1971, 1972, and 1973 4°C isotherms superimposed on the original map (disregard inset of Greenland in this context).

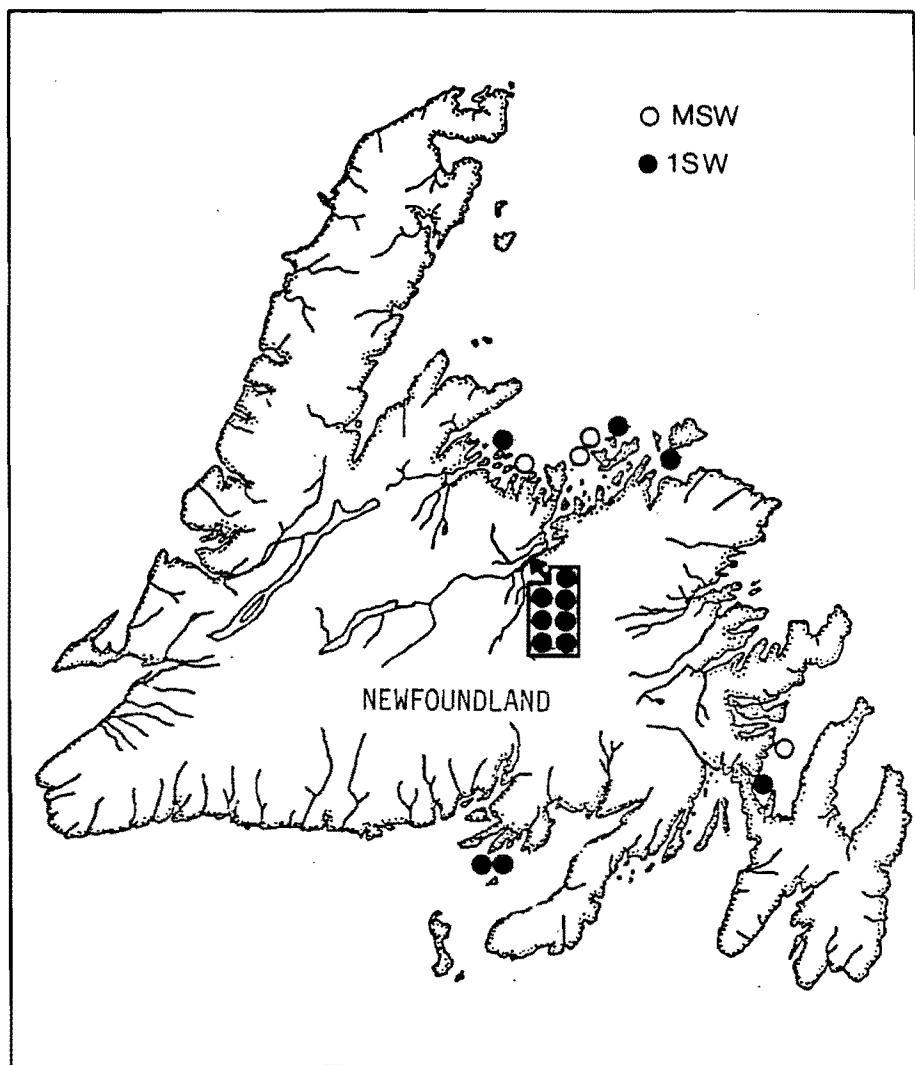

Fig. 4. Distribution of captured 1SW and MSW salmon that were tagged as smolts in the Exploits River (Noel Paul's Brook counting fence) in 1978.

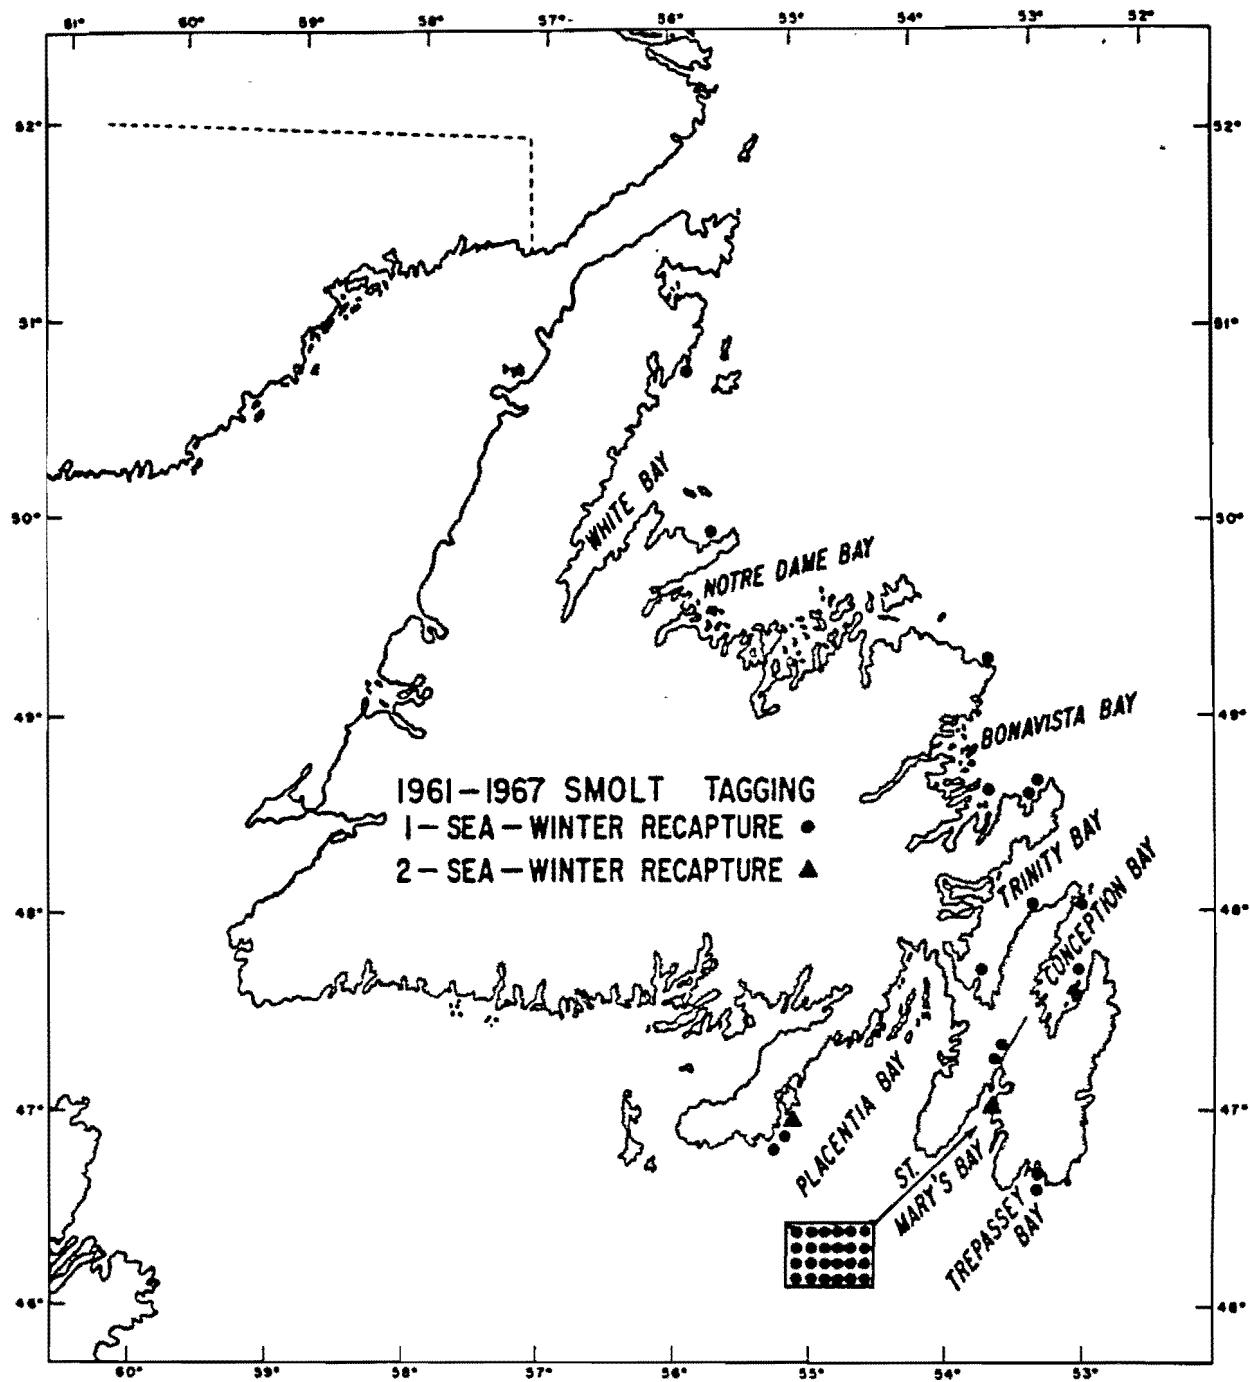

Fig. 5. Distribution of captured 1SW and MSW salmon that were tagged as smolts during 1961-67 in North Harbour River, St. Mary's Bay, Newfoundland. From Lear and Day (1977).

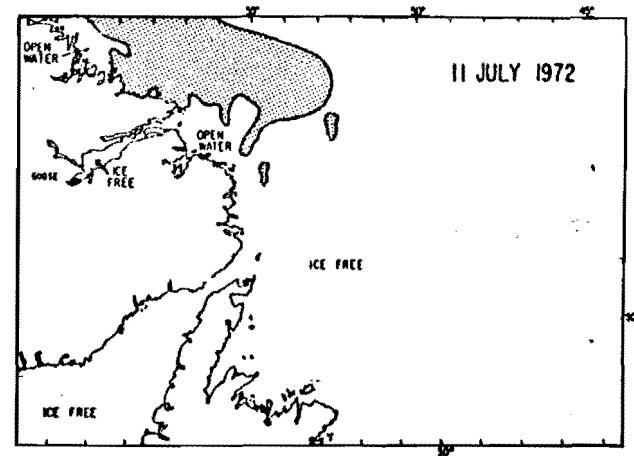

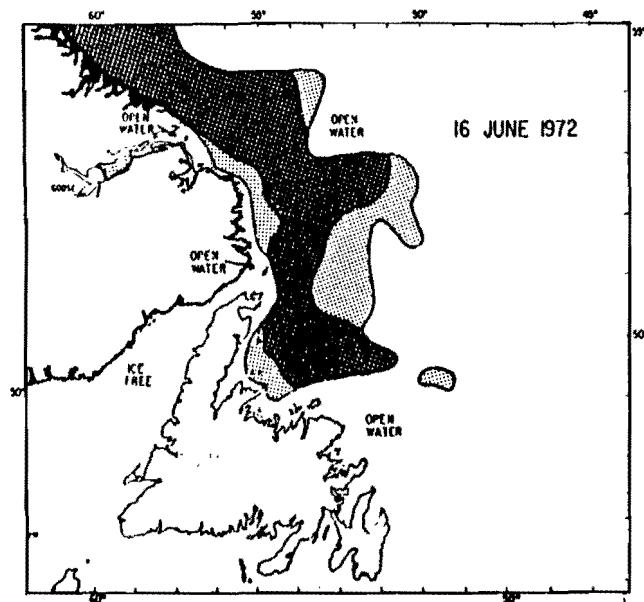

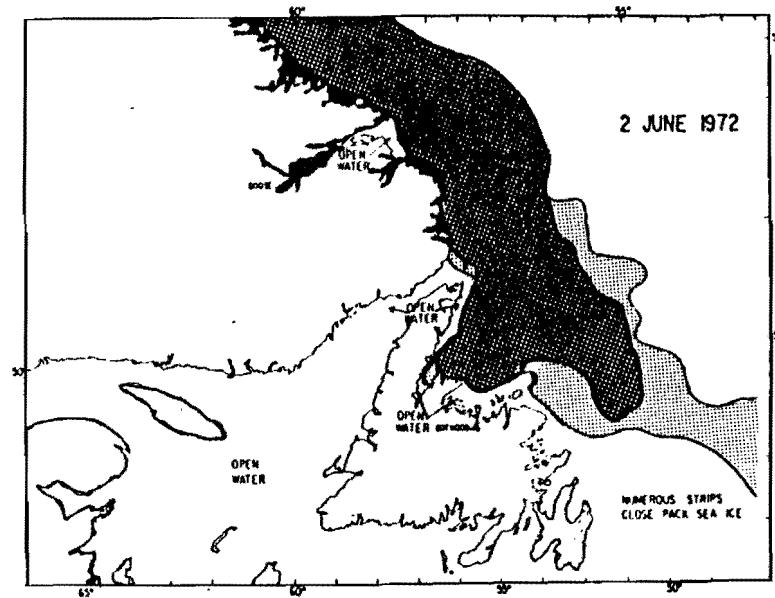

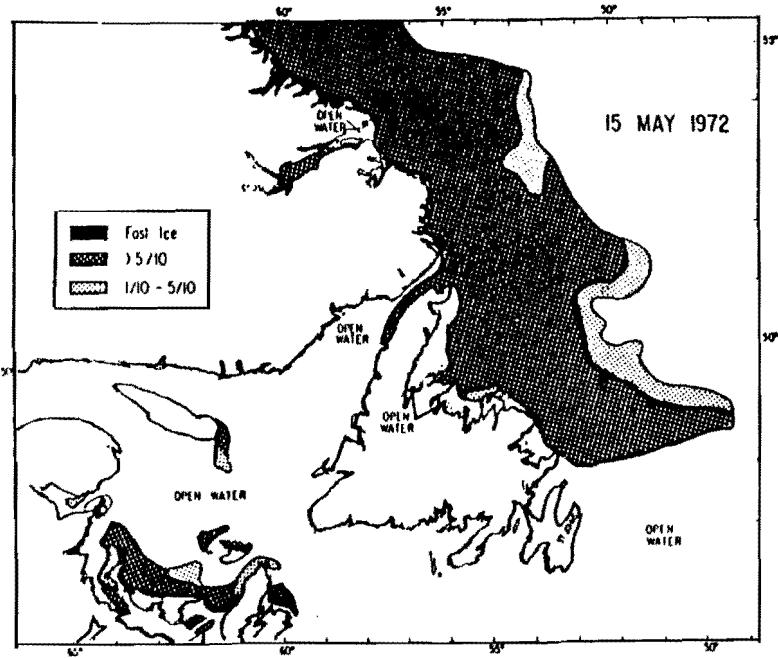

Fig. 6. The distribution of ice for Newfoundland during the 1972 commercial salmon fishery. Fractions indicate proportion of sea covered by ice. From Reddin and Day (1980).

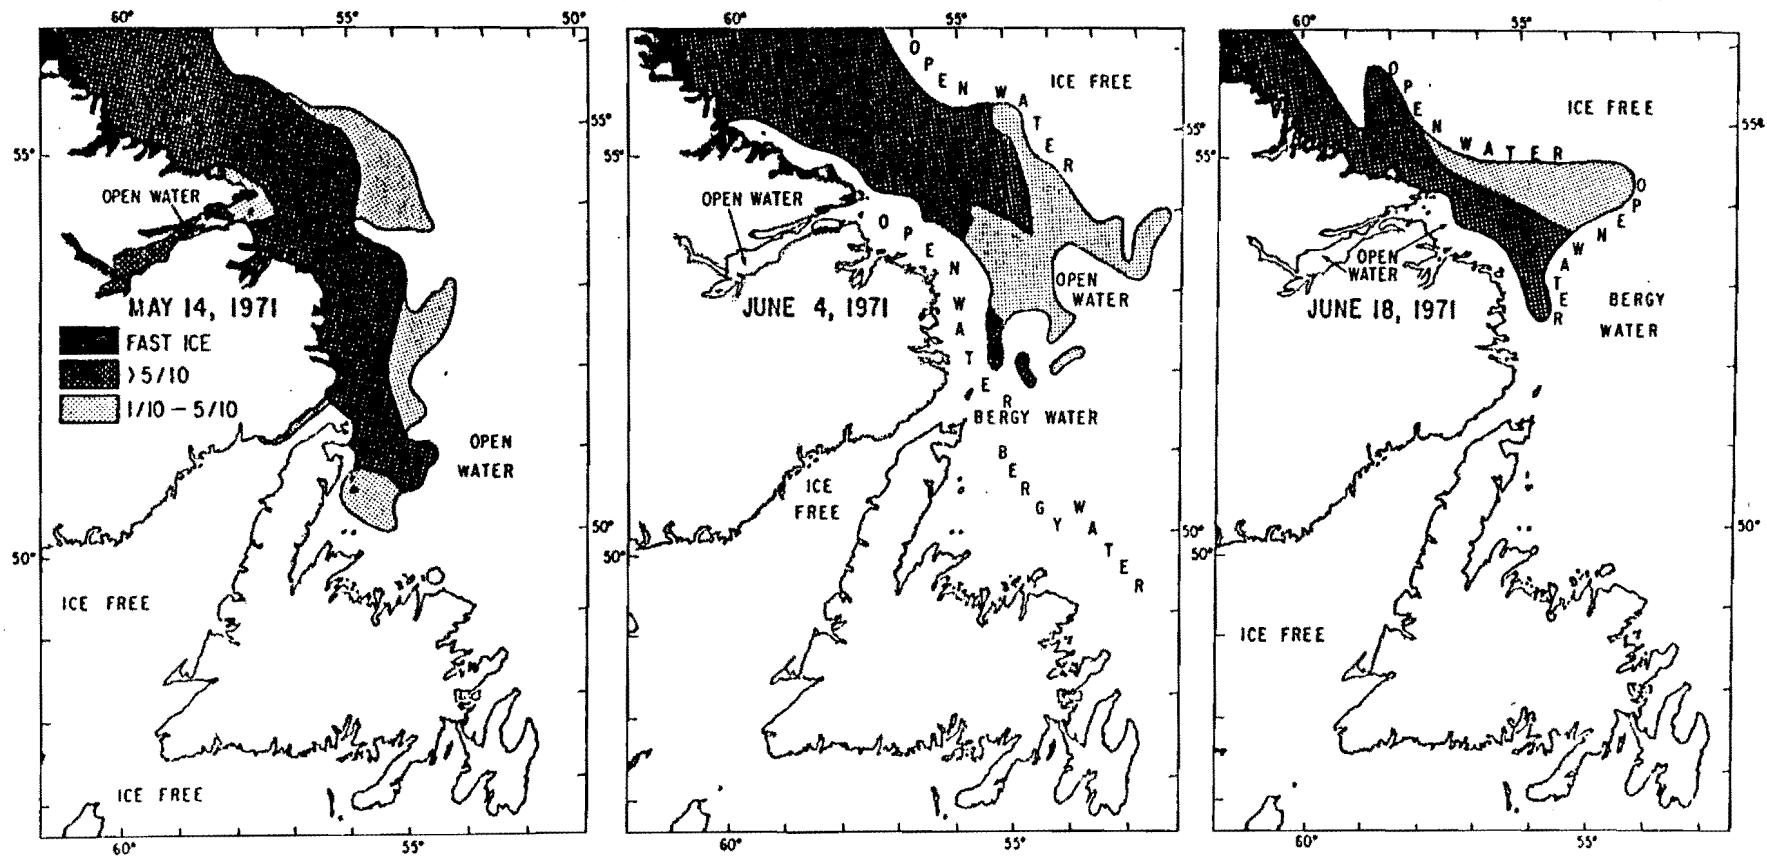

Fig. 7. The distribution of ice for Newfoundland during the 1971 commercial salmon fishery. Fractions indicate proportion of sea covered by ice. From Reddin and Day (1980).

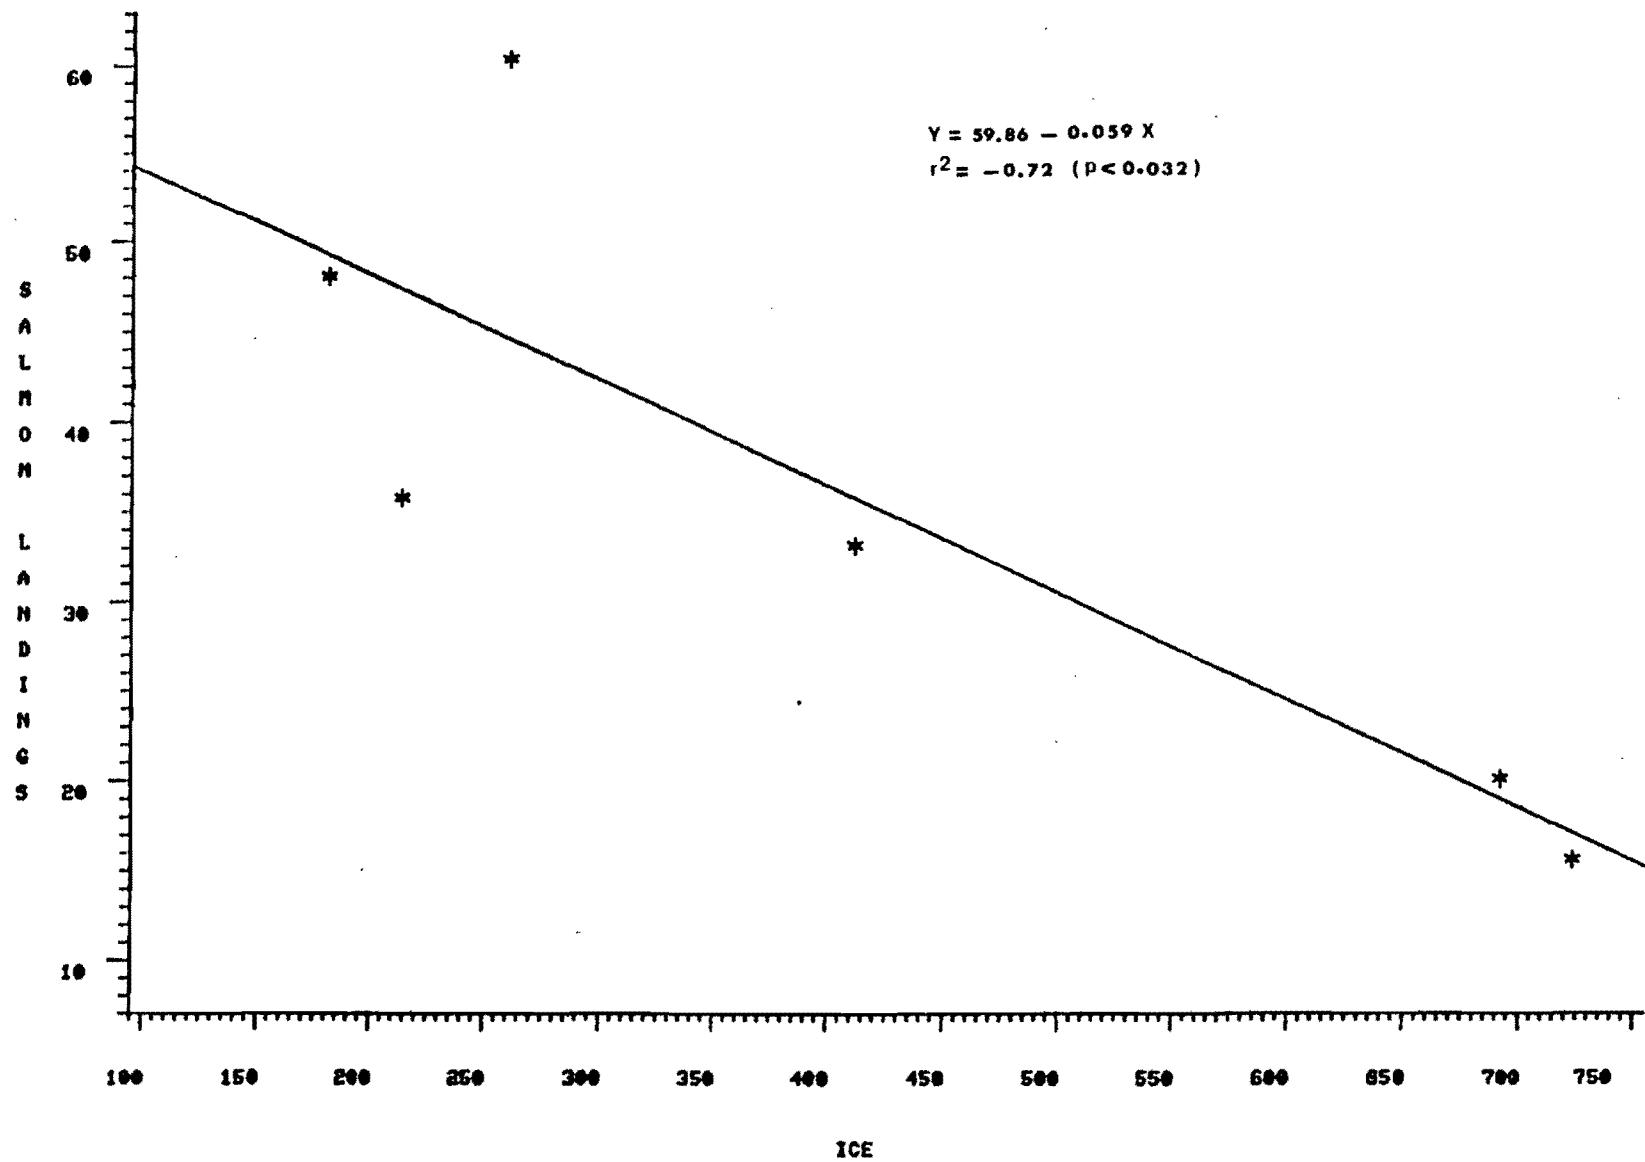

FIG. 8 REGRESSION OF NAIN SALMON CATCH ON ICE AREA

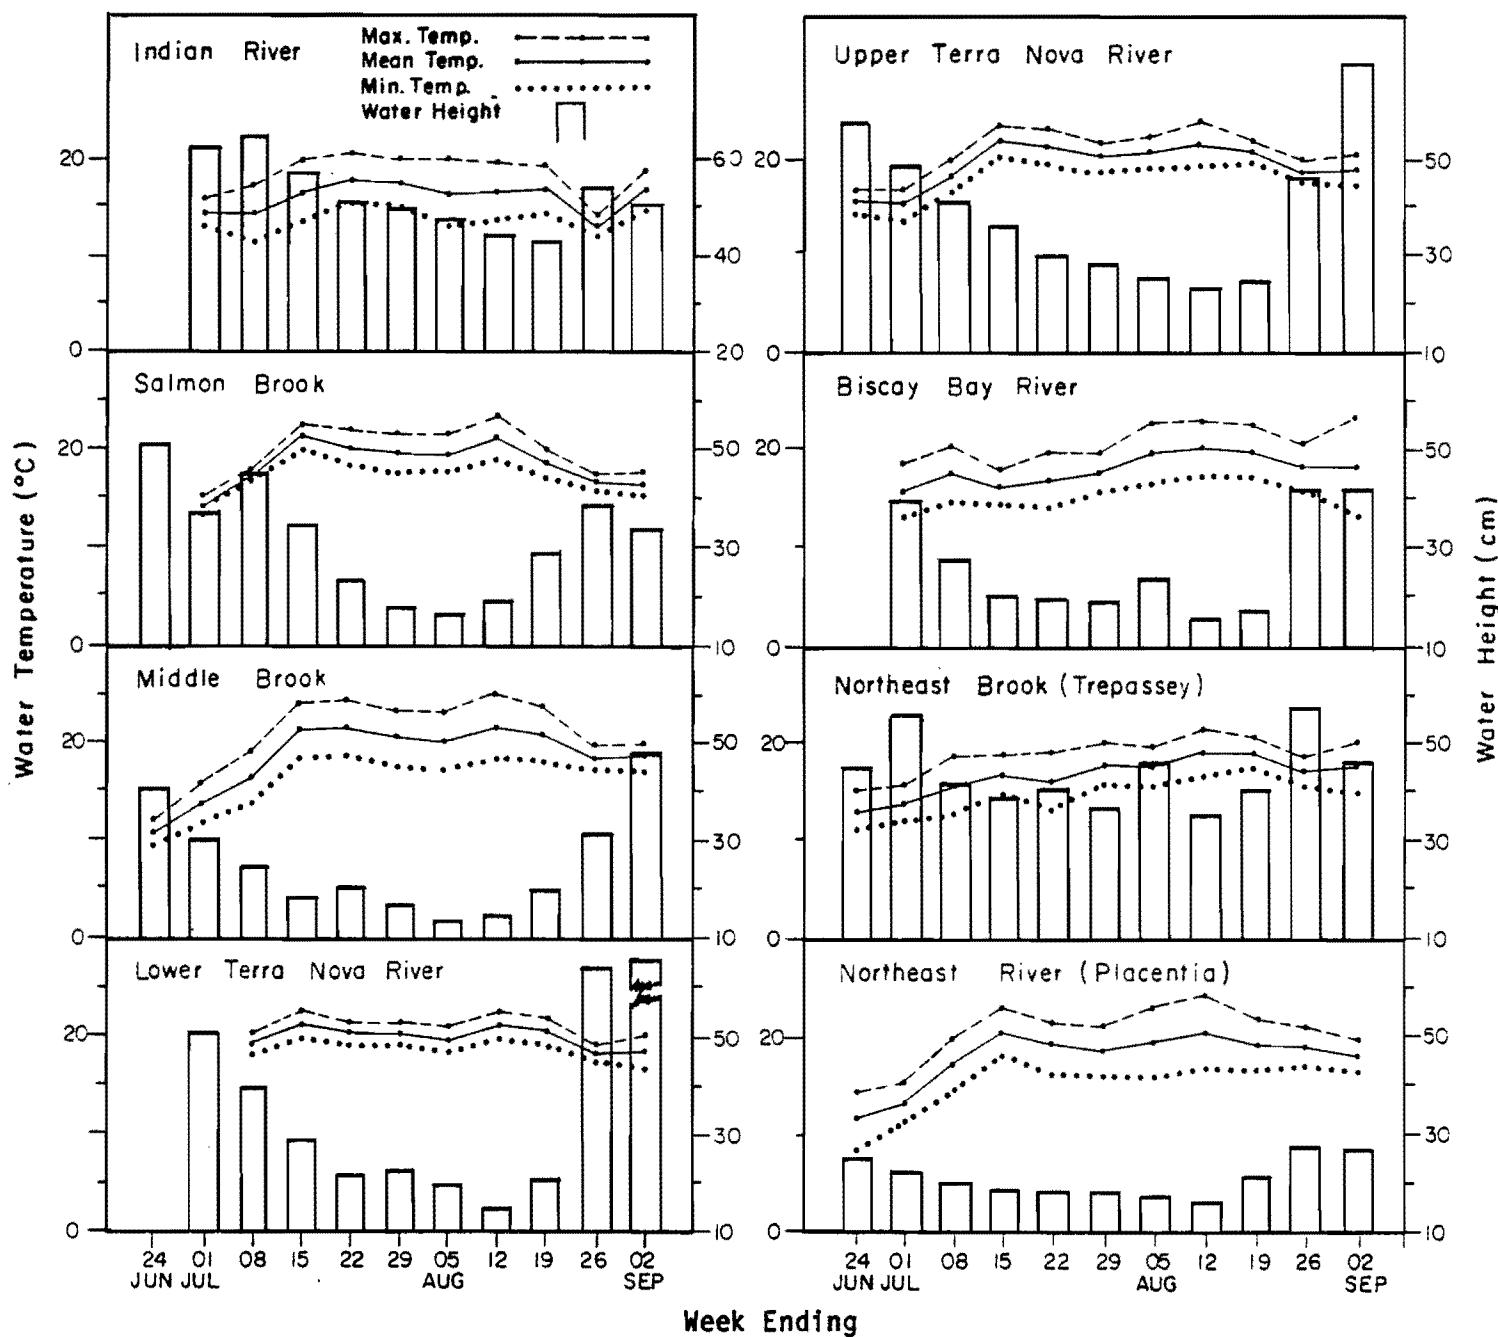

Fig. 9. Weekly temperature and water height data collected at fishways and counting fence installations, 1984.

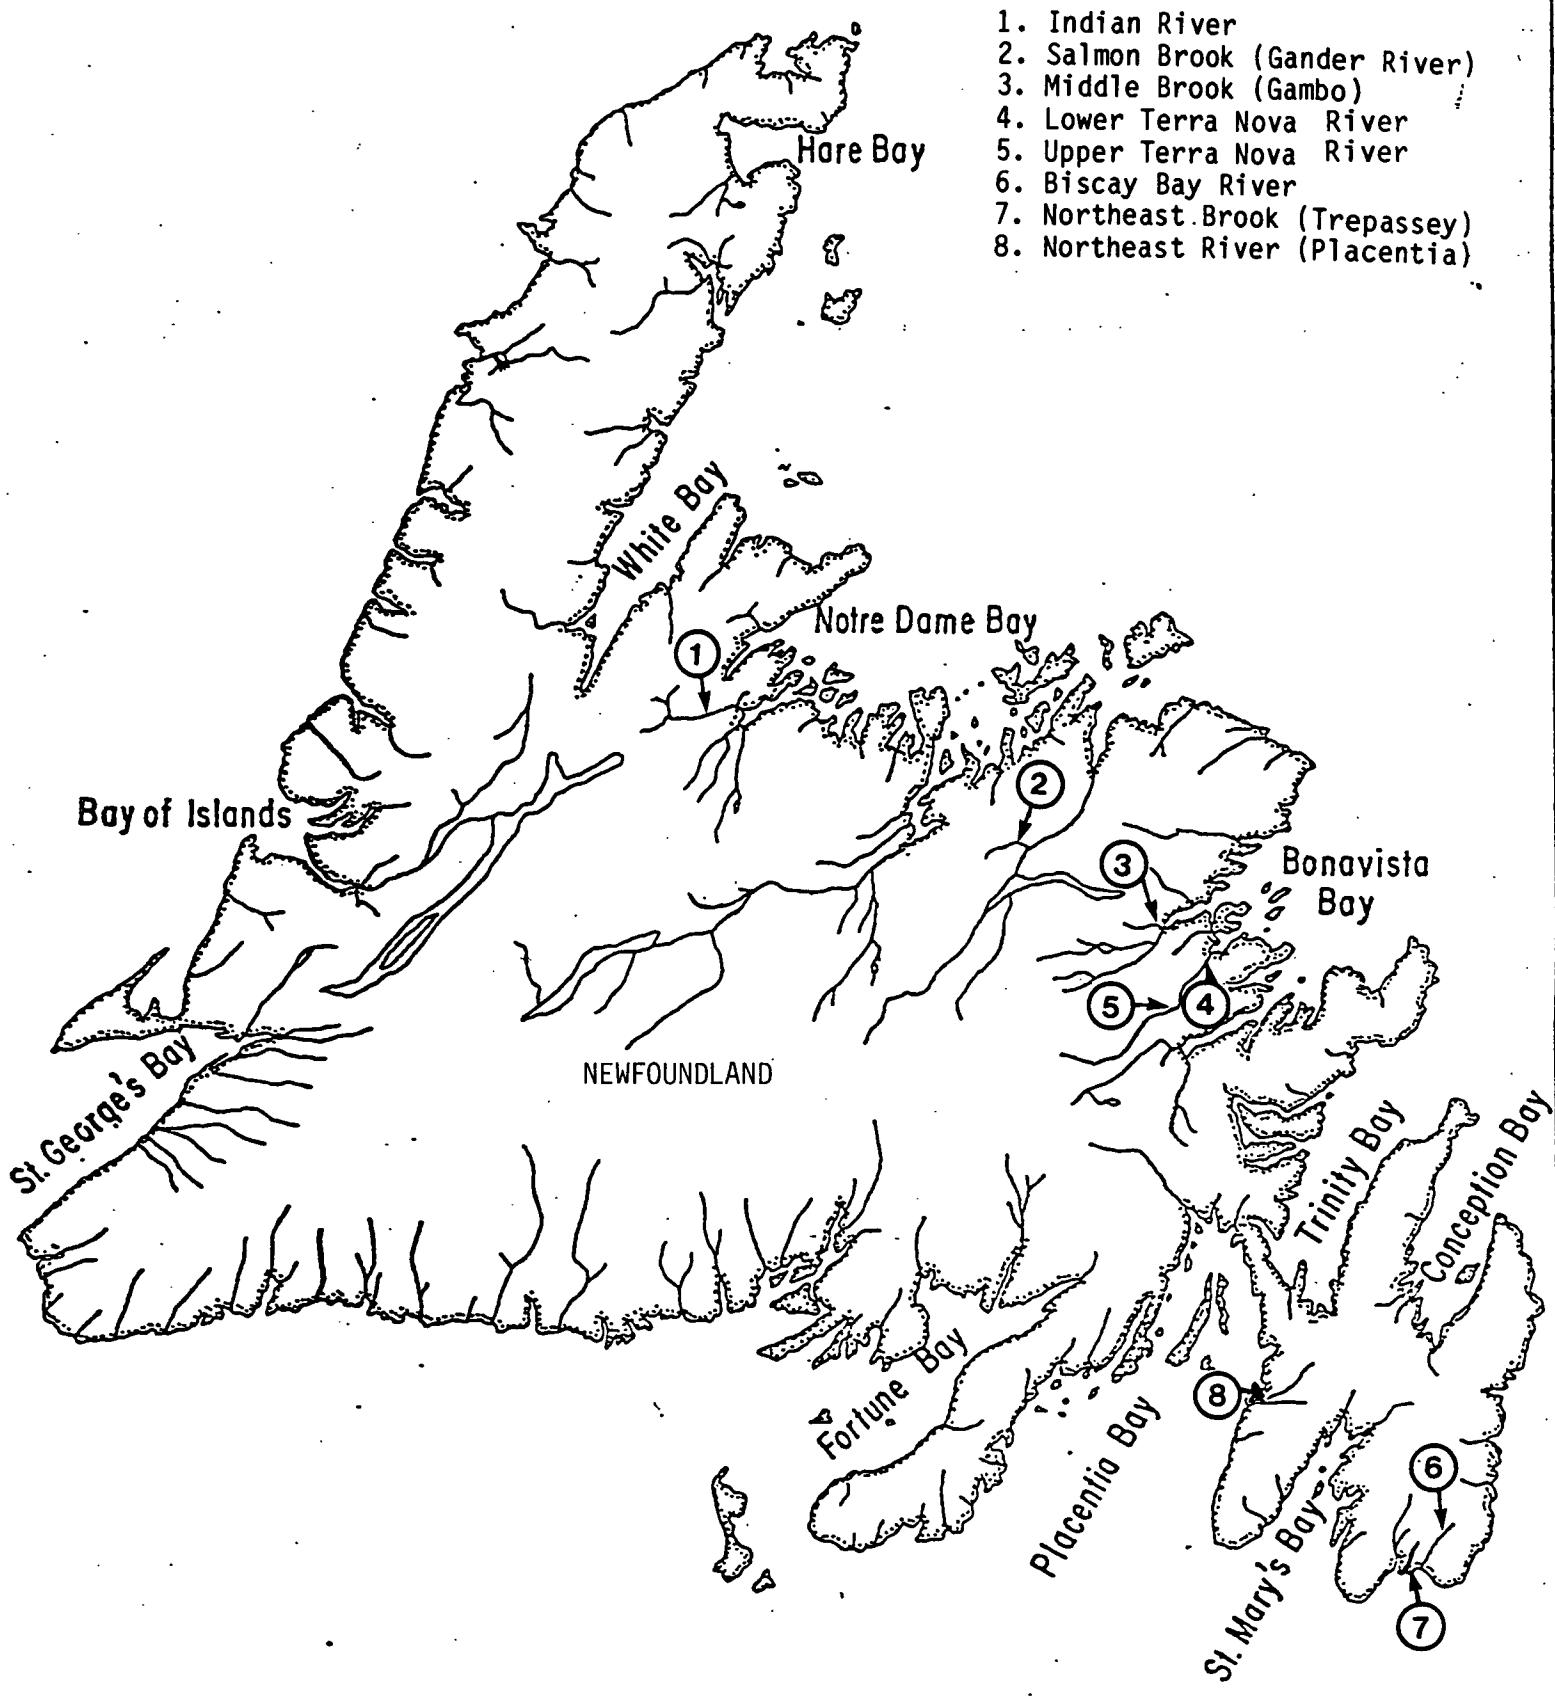

Fig. 10. Locations of fishways and counting fence installations (Biscay Bay River and Northeast Brook, Trepassey) where adult Atlantic salmon counts were obtained in 1984.
