## 4Yn COD (MAY-DECEMBER): STATUS REVIEH FOR THE 1984 FISHING YEAR

by
S.J. Smith and A.F. Sinclair

Marine Fish Division
Department of Fisheries and Oceans
P.0. Box 1006

Dartmouth, Nova Scotia B2Y 4A2

1
This series documents the scientific basis for fisheries management advice in Atlantic Canada. As such, it addresses the issues of the day in the time frames required and the Research Documents it contains are not intended as definitive statements on the subjects addressed but rather as progress reports on ongoing investigations.

Research Documents are produced in the official language in which they are provided to the Secretariat by the author.

1 Cette série documente les bases scientifiques des conseils de gestion des pèches sur la cōte atlantique du Canada. Conme telle, elle couvre les problèmes actuels selon les échéanciers voulus et les Documents de recherche qu'elle contient ne doivent pas être considērés comme des énoncés finals sur les sujets traités mais plutōt comme des rapports d'étape sur les études en cours.

Les Documents de recherche sont publiés dans la langue officielle utilisée par les auteurs dans le manuscrit envoyé au secrétariat.

## ABSTRACT

Nominal catch of cod in 4Vn (May-December) was $10,527 \mathrm{t}$ in 1984, an increase of 1185 t from 1983. Landings for all gear categories with the exception of longliners increased from last year. The decrease in longline catch was slight compared to decreases in previous years.

This report summarizes available information for this fishery in 1984. Samples were obtained from all major components in the fishery allowing for comparisons of age composition of landings between gear types.

RESUME
En 1984, la prise nominale de morue dans la zone 4 Vn (mai-décembre) s'est établie à 10527 t , soit 1185 t de plus qu'en 1983. Les débarquements ont augmenté pour toutes les catégories d'engins de pêche, à l'exception des palangriers. Toutefois, la diminution de la prise dans le case de la pêche à la palangre est faible si on la compare aux baisses des années précédentes.

On trouve dans le rapport un résumé des informations disponibles sur la pêche à la morue (année 1984). Des échantillons obtenus des principaux participants à cette pẹche ont permis d'établir des comparaisons entre les types d'engins de pêche et l'âge des poissons débarqués.

## INTRODUCTION

A complete review of the management history of 4 Vn (May-Dec) cod stock for the period 1974 to 1983 was given in Sinclair and Smith (MS 1984). The following is a review of developments since 1983. In 1983 CAFSAC (Adv. Doc. $83 / 19$ ) suggested that a catch of $14,000 \mathrm{t}$ in 1984 would roughly correspond to the $2 / 3$ EMSY catch. This advice was based on the results of a general production analysis and the apparent strength of the 1977 year class from the survey and commercial (longliner) catch-at-age information. Nominal catch in 1983 was $9342 t$, substantially below the TAC and approximately 3000 t lower than in 1982 (Table 1). Catch by longlines in 1983 was over 2100 t lower than in 1982 and 4700 t lower than the record high level in 1981 (Table 2).

In a review of the status of the stock for 1983 Sinclair and Smith (MS 1984) presented a reanalys is of the general production model which resulted in a calculated $2 / 3 E_{\text {MSY yield }}$ of $10,200 \mathrm{t}$. The fit of the model to the data used was admittedly poor with an r-square of 0.46 . Estimated fishing mortal ity for $5+/ 6+$ from surveys and CPUE-at-age for longliners indicated that fishing mortalities in recent years were slightly above $F_{0.1}=0.20$. Concern was also expressed over the possible effect of increasing otter trawl catches on the abundance of younger year classes which were not fully recruited to the longline gear.

Based on the apparent strength of the 1977, 1979 and 1980 year classes CAFSAC (1984, Adv. Doc. 84/14) suggested that the $4 V n$ (May-Dec.) cod stock was still above equilibrium but were unable to quant ify how much the stock was above this level. Therefore it was suggested that a catch of $10,000 \mathrm{t}$ in 1985 would approximately correspond to $2 / 3$ EMSY. AGAC set the 1985 TAC at $12,000 \mathrm{t}$.

## Nominal Catch

The nominal catches by country for the period 1970-1984 are presented in Table 1. Total catch for the same period is plotted in Figure 1. There were no landings reported by countries other than Canada for 1984. Total landings for 1984 were up by 1185 t from 1983. This increase was shared by the otter trawls, seines and handlines (Table 2). The longliner catch decreased for the third year in a row, but the decrease in 1984 was slight compared to the two previous years. The percent composition of catch by gear over the period 1970-1984 is shown in Figure 2.

The original 1984 quota for the mobile gear <65' was 1900 t . According to the quota reports this was exceeded on 1 August report and the fishery was declared closed August $12 t h$. In the September 12 th report 1200 $t$ was reallocated to the mobile gear <65' from the fixed gear <65'. This new quota of 3100 t was exceeded and the fishery was closed as of the first of November.

Landings by gear and tonnage class are presented for 1983 and 1984 in Table 3. As was noted in 1983 the TC 1-3 otter trawlers which roughly correspond to vessels $<65^{\prime}$ are becoming a major part of the otter trawl fishery. Substantial increase in landings by TC2 vessels occurred in 1984 compared to the previous year. For longliners, only the TC2 vessels showed an increase in catch.

The monthly breakdown of landings by gears given in Tables $4 a$ and $4 b$ do not show any appreciable change in pattern from past years. Landings for longlines, otter trawls and seines are relatively high in the spring, decrease over the summer and then increase again in the fall.

## RESEARCH SURVEY RESULTS

Results from the analys is of the comparative fishing experiments given in Fanning (MS 1985) and discussed by CAFSAC indicate that no conversion factors are necessary for catches of cod by the A.T. Cameron and the Lady Hammond. Also, since there are still questions extant regarding the comparison of the Lady Hammond and A. Needler it was deemed inappropriate to apply a conversion factor to catches of cod by these two vessels at this time. We have avoided the problem of differences in sampling unit sizes between the gear used by the two vessels by considering stratified mean catch/tow as our index of abundance rather than total biomass estimates.

The mean numbers/tow, total number/tow and total weight/tow for the 1970-1984 summer research cruises by age are presented in Table 5. Results for 1970-81 inclusive are from the A.T. Cameron cruises. The Lady Hammond conducted the 1982 cruise and the last two cruises (1983-84) were made by the A. Needler.

The 1977 year class (age 7) no longer appears to be exceptionally large in the 1984 survey compared to the 1974 and 1975 year classes at the same age. The 1979 and the 1980 year classes cont inue to look good in comparison to previous year classes at the same ages. The 1981 year class also shows promise. The 1978 year class does not appear to be exceptional, but is having a large impact on the commercial catch (see below).

The total mean number/tow shows little change from the previous year but the total weight/tow has increased substantially, reflecting the greater proportion of older fish caught in the 1984 survey ( $9+$ ).

The estimates of mean number and mean weight per tow are plotted in Figure 3. The estimates for 1981 cont inue to appear to be anomalous in comparison to adjacent years. A comparison of mean numbers per tow by strata (Table 6) shows that 1981 was also unusual for having substant ial numbers of cod caught in stratum 40. This occurrence was recorded by both vessels in the comparative survey that year.

The percent contribution of specific year classes (1974, 1975, 1977, and 1978) to the total survey within the three strata in $4 V n$ are plotted in

Figure 4. Details concerning depth range and percent of area contained within each stratum are given in Table 6. For the 1974, 1975, and 1977 year classes the percent contributions peaked first in the shallow strata (42), then in stratum 41 and finally in stratum 40 . This indicates that cod move to deeper waters as they grow older.

Anecdotal information from Department staff in Cape Breton indicated that longliners in 1981 and, in 1982 to a lesser extent, were fishing in the deep waters close to the edge of the Laurentian channel. This was at a time when the deepest stratum was dominated by the larger 1974 and 1975 year classes. Recently, it appears that these vessels have been concentrating in the shallower water in Sydney Bight. The 1984 survey indicates an absence of large amounts of older fish in the deeper stratum.

Commercial Catch at age
Sampling coverage of the commercial catch in 1984 was the best for this stock to date. All major gears were covered and for the first time a comparison can be made between the age composition of the fish landed by each of these gears. The data used to generate the age-length keys are summarized in Table 7.

The length frequencies from the handline and longline (tonnage class 1) samples were judged to be similar and information from both gears were combined to estimate the age composition of the landings for each of these gears.

The longliner catch at age is at present our only time series for this stock and is presented in Table 8 for the years 1970 to 1984. Although 1975 and 1974 year classes are still contributing to the catch the 1977-1979 year classes predominate.

The mean weights at age for the longliner catch are given in Table 9. Weights at age in 1984 for the younger year classes appear to be in line with previous years while the weights of the 1974 and 1975 year classes appear to be low in comparison to previous years.

A comparison between the catch at age for the major gears is presented in Table 10 and in Figure 5. The longlines have a higher proportion of older fish (age 8-11) than the other gears while the otter trawl catch was dominated by ages $5-6$. In last year's report concern was expressed over the effect that increased otter trawl catch could have on the age groups not yet fully recruited to the longliner gear. Figure 5 shows that the otter trawls concentrate heavily on the younger age classes (ages 4-7) which may result in a decrease in the future availability of older fish to the longliner fishery.

## Catch per Unit Effort

The CPUE estimates for longliners TC2 for 1968 to 1984 are given in Table 11. The estimate for 1984 shows a slight increase over that for 1983. However, the number of $\log$ book returns from longliners continues to be small.

## General Production Model

A general production model was fitted to nominal catch and an effort series derived from the research survey mean weight/tow for 1970 to 1981 in last year's document (Sinclair and Smith MS 1984). Now that the comparative fishing analys is by Fanning (MS 1985) has concluded there was no difference between the two vessels for cod we have extended the above general production analys is to include data up to 1984 (Table 12 and Figure 6). The r-squared has changed very little from that obtained with 1970-1981 data (0.46) and catches have been fairly stable for recent years (1980-1984) with respect to the equilibrium yield reference curve (Figure 6b).

## Mortal ity Estimates

Estimates of total mortality were calculated from survey catch per tow at age (Table 5) and longline CPUE at age (Table 13) for the period 1980-1984. These estimates were averaged and are presented in Table 14 for age groups $4+/ 5+$ to $10+/ 11+$. The mortal ity est imates indicate full recruitment at age 5 for the surveys and age 7 for the commercial data. Estimates of total mortal ity for fully recruited age groups were obtained by averaging $5+/ 6+$ and $6+/ 7+$ estimates for surveys and $7+/ 8+$ and $8+/ 9+$ estimates for the commercial data. Estimates of mortality beyond these age groups were not used due to the small numbers of fish caught a these ages which would make the estimates unreliable. Assuming that natural mortality equals 0.2 estimates of total mortality for fully recruited age groups imply that fishing mortalities are equal to 0.36 from the longline data and 0.46 from the survey data.

## SUMMARY

Abundance indices from the research vessel survey indicate fairly stable conditions for this stock with signs of potent ially good recruitment from the 1979, 1980 and 1981 year classes. Surveys for the adjacent stocks (4VsW, 4T and 4RS-3Pn) give similar indications for these same year classes, with the exception of 1981 for 4 VSW .

Commercial catch per unit effort (CPUE) from the longliners increased slightly in 1984 over 1983. The number of logbooks returned remains small. Tonnage class (TC) 1 vessels which land the largest portion of the longline catch are not required to carry logbooks. Therefore, trends in this index remain difficult to interpret.

Estimates of fishing mortality from summer research surveys and longline CPUE at age suggest that fishing mortalities in recent years have been above $F_{0.1}=0.20$. Average estimates for the period 1980-1984 for fully recruited age groups indicate fishing mortalities of 0.36 from the commercial catch rates and 0.46 from the research surveys.

This is the first year for which age composition has been available for all of the major gears in the fishery. The commercial age composition indicates that the otter trawlers are concentrating on younger age-classes than longliners. The recent trend of increasing allocations to otter trawlers may reduce future yields to the longliners, especially at current levels of fishing mortality. Further sampling of all gears will aid in assessing the impact of the otter trawl fishery over the next few years.

The general production model used in the last three assessments was updated to include catch and effort derived from the survey indices of the last three years. Results suggest a long-term sustainable yield at the reference fishing effort level of $2 / 3 \mathrm{E}_{\mathrm{MSY}}$ (effort at MSY) of $10,500 \mathrm{t}$. This estimate differs little from the previous one, although the fit to the model remains poor.
