## Status of the Atlantic Cod Stock on Georges Bank, NAFO Division 52 and Statistical Area 6, 1984

by

J.J. Hunt and K.G. Waiwood<br>Marine Fish Division<br>Fisheries and Oceans<br>St. Andrews, N.B. EOG 2XO

1
This series documents the scientific basis for fisheries management advice In Atlantic Canada. As such, it addresses the issues of the day in the time frames required and the Research Documents it contains are not intended as definitive statements on the subjects addressed but rather as progress reports on ongoing. investigations.

Research Documents are produced in the official language in which they are provided to the Secretariat by the author.

1 Cette série documente les bases scientifiques des conseils de gestion des pêches sur la côte atlantique du Canada. Comme telle, elle couvre les problemes actuels selon les echéanciers voulus et les Documents de recherche qu'elle contient ne doivent pas etre considêrês come des enoncés finals sur les sufets traités mais plutôt comme des rapports d'étape sur les Etudes en cours.

Les Documents de recherche sont publiés dans la langue officielle utilisée par les auteurs dans le manuscrit envoye au secretariat.

#### Abstract

Status of the Atlantic cod stock in Division 52 and Statistical Area 6 is reviewed incorporating 1984 data. Total catch in 1984 was 39000 tons and Canadian catch was 6000 t, the lowest levels since 1980 and 1976, repectively. Catch rates also showed a decline in most gear components and research surveys were unchanged from the low 1983 levels. Sequential population analysis was carried out on the catch-at-age matrix for 1976-84 and indicated a fishing mortality of 0.6 in 1984 which is well above both the F 0.1 and $F$ max levels. Projection of the 1986 catch with fishing at the $F 0.1$ level gives a yield of about 11000 t . Size of recruiting year-classes will have a substantial impact on future catches form this stock.

## Résume

On a fait le point sur l'etat du stock de morue de l'Atlantique dans la Division 52 et la zone statistique 6 en ajoutant les donntes de 1984. Les prises totales en 1984 ont eté de 39000 tonnes, dont 6000 t de prises canadiennes, montants les plus bas depuis 1980 et 1976 respectivement. Les prises ont aussi chute pour la plupart des engins de pêche, et les indices des relevés des croisières de recherche sont restés inchangés par rapport aux faibles niveaux de 1983. Une analyse séquentielle de la population portant sur la matrice des prises par âge de 1976 à 1984 a indiqué une mortalite par pêche de 0,6 en 1984, ce qui est bien au-dessus des niveaux $F_{0,1}$ et $F_{\text {max }}$. Les prises de 1986, en supposant un niveau $F_{0,1}$ par pêche, sont estimées à environ 11000 t . La taille des classes d'age de recrutement influera beaucoup sur les futures prises dans ce stock.

## Introduction

The size of the cod population in NAFO Division $5 Z$ and Statistical Area 6 (Fig. 1) was first evaluated by Brown and Heyerdahl (1972) through the examination of research survey data and commercial catch rates. Serchuck et al (1977, 1978) conducted virtual population analysis of the catch data but considered results to be suspect because of uncertainties in the reliability of reported catch statisitics (Serchuck 1979, 1980, 1981, 1982). Catches since 1977, when foreign fleets were subject to 200 mile jurisdiction by the USA, are thought to be more reliable and the amount of mis- or under-reporting is assumed to be nominal for the period 1978-84. There were no reported landings by foreign fleets since 1978.

Hunt and Waiwood (1984), in a review of stock status, suggested a probable fishing mortality of 0.4 in 1983. However, their report was not based on a formal assessment due to an inadequate time series for catch at age in the fishery.

The present report considers the catch data from 1978-84 and subjects these data to sequential population analysis (SPA) and attempts to estimate stock structure. Cod in Division 52 are taken by both Canada and the USA and all data relating to USA catches, CPUE and research vessel surveys were were provided by the National Marine Fisheries Service (NMFS) through Dr. Frederic Serchuck at the Woods Hole, Mass., Laboratory.

Trends in Reported Landings
Annual Landings
The USA has been the main harvester of cod in Division 52 and Statistical Area 6, with high foreign landings in the mid-1960 period (Table 1, Fig. 2). Catch by Canada was also high in this period and peaked at 15601 t in 1966. Total landings declined to about 20000 t in 1976 but then increased to a maximum recorded value of 57195 t in 1982.

Total landings in 1983 were 48888 t , a decline of over 8000 t from 1982, and fell by an additional 10000 t to 38676 t in 1984. This is about $68 \%$ of the 1982 level and reflects a sharp reduction in landings by Canada in both 1983 and 1984.

Fishery by Country and Gear
The USA cod fishery is dominated by otter trawlers (Table 2) that operate throughout Division 5Z. Catches by other gears such as gill nets, Danish seines and longlines have accounted for $10-15 \%$ of the total USA catch. A substantial "recreational" fishery also exists for this stock but there are presently no estimates of the amount caught, although it may exceed 10000 t in some years.

Canadian catches of cod are confined to the "northeast peak" of Georges Bank (NAFO unit areas 5ZEj and 5ZEm) and occur from April through November. Landings have been dominated by otter trawlers until 1984 (Table 3, Fig 3). This gear took $70 \%$ of the total catch in 1982, fell to $57 \%$ in 1983 and was at a low level of 737 t in 1984. Catches of longliners increased from about
$30 \%$ of the total in 1982 to about $85 \%$ in 1984. A trend for smaller TC 2 and 3 vessels to operate in this fishery has also been noted in recent years.

Preliminary Canadian catches from quota reports in 1985 show an increase in otter trawl catches to about 5500 t at the end of August and about 1300 t by longline.

Age Composition of the Commercial Catch
Sampling Intensity
Sampling coverage of the Canadian fishery averaged about one sample per 1000 t landed since 1980 and is biased towards otter trawl catches (Table 3). Only 7 samples, all from longline gear, were taken in 1984 although total catch was less than 6000 t. From 400-800 cod are aged each year.

USA sampling has increased substantially since 1980 , when 70 samples were collected, and is now at a level of over 150 samples per year. Sufficient samples are collected to estimate catch-at-age by gear and quarter and market category for USA landings.

Age Composition of the Commercial Catch
Estimated removals at age prior to 1978 given by Serchuck (1977) are probably under-estimated and are not considered reliable because of suspected under-reporting of catches by foreign fleets. Catch composition of USA commercial landings for 1978-84 were provided by NMFS.

Numbers at age estimated by $0^{\prime}$ Boyle (1983) were based on otter trawl samples only and as a result the data were re-analysed to take into consideration samples from longline gears. Age composition was estimated by gear and quarter and summed to annual totals for 1978-84. In some cases it was necessary to combine gears and/or quarters were sampling was inadequate. Percent at age from Canadian landings is given in Table 4. Total removals, in thousands of fish, by Canada and the USA are given in Table 5.

Commercial catch sampling by Canada included observation of weight for both round and gutted fish. A total of over 1500 measurements were taken from 1982-84 and these data used to regress length on weight. The resultant relationship gave an $a=0.0000163$ and $b=2.9048$ with gutted weight in kilograms and length in centimeters. This compares to values of $a=0.000008104$ and $b=3.0521$ for USA autumn surveys. Data from the surveys have not been modified since 1977 and were used to estimate numbers in the USA catch. The Canadian length weight relationship was assumed to be a better estimate of the commercial fishery and was used to estimate the Canadian removals at age for 1978-84. A comparison of calculated weight at age using the two values for $a$ and $b$ is given in Table 6 and summarized in Figure 4. In the central part of the commercial length range, the USA parameters estimate a higher gutted weight at length. Mean weight and length at age for combined Canadian and USA commercial catches are given in Tables 7 and 8.

Age groups 2-5 account for most of the yield but a difference in the age composition between Canada and USA is apparent (Fig 5). USA catches show
a higher proportion at age 2 in all years and in recent years this age group has accounted for more than twice the percentage taken by Canada at age two. These differences in age composition may be related to interpretation of otoliths and there appears to be a tendency for Canada to age fish older relative to USA ages at the same length. Differences in spatial, temporal length distribution of catches between countries may also be factors. An exchange of ageing material and discussion between USA and Canadian age readers has been initiated in an attempt to resolve this discrepancy. Pending results of this study, it was assumed that the best estimate of catch at age was derived from the sum of the independent USA and Canadian values and these data were therefore used as the input for SPA.

## Stock Abundance Trends

## Research Surveys

Random, depth-stratified bottom trawl surveys have been conducted by the USA in the autumn since 1963 and a spring survey added in 1968. A summer survey was conducted from 1977 to 1981. One survey in Division 5Ze was completed by Canada in March, 1984. Mean catch per tow in numbers by age group for each of the USA surveys is given in Table 9 and the mean catch per tow in numbers and weight in Table 10, Fig. 6. No adjustment for different gears or vessels used during the time series has been made. The spring survey used the larger "Yankee 41" trawl from 1973-81 and considerable differences in catch per tow could be anticipated. Total net opening of the "41" trawl is about 1.7 times the opening of the "Yankee 36". Based on the peak season for the commercial fishery, the spring survey is assumed to be a current year index of abundance versus the autumn survey from the previous year.

The spring survey has shown a steady decline in $0+$ numbers since 1981 and was at the lowest observed level in 1984 but increased to the second highest level since 1974 in the preliminary 1985 survey results. The autumn survey has also shown a steady decline since 1981 but appears to have leveled off in the 1984 survey. Serchuck (pers. comm.) notes that catches of all species were anomalously low in the 1982 autumn survey which may indicate a change in availability and this may also be a factor in the 1983 survey.

## Commercial Catch Rates

Catch rates for Canadian TC 4 and 5 otter trawlers, landing cod as the primary species during July-September, are given in Table 11, Fig. 7. Rates were relatively stable at about 0.25 t/hour from 1970-76 and then increased by a factor of about three in 1977. Side trawlers were not used in 1983 and 1984. Rates for the TC 5 stern trawlers were stable in 1981-83 at a level of about 0.8 t/hour but fell to 0.28 in 1984 which corresponds to a tenfold decrease in otter trawl catch from 1983 to 1984. However, the decline in catch and CPUE may reflect a decision by industry not to deploy
vessels in the Georges Bank area. Discussions with Port Samples indicate that otter trawlers experienced low catches early in the spring and did not return to the area during the historical peak of the fishery when rates may have been higher. The low level of fishing effort would be a factor in the 1984 catch rates.

An index of CPUE in t/1000 hooks fished for TC 2 and 3 longliners landing $>50 \%$ cod is shown in Table 12 for 1972-84. A decline in recent years, from the 1979 high of 0.69 , is apparent, but the rate in 1982-84 has been stable with no change between 1983 and 1984.

Unpublished data on USA catch rates were provided by Serchuck and are reproduced in Table 13, Fig. 8. Landings by TC 2, 3 and 4 otter trawlers for all trips and $>50 \%$ cod trips are given. Catch rates in all categories show a general decline between 1978 and 1983 and, without exception, the catch rates in 1984 were the lowest since 1978.

## Survey Index of Recruitment

Indices of recruitment were obtained from the autumn survey catch per tow at ages 0, 1 and 2 for the 1962-83 year-classes. The catch per tow at age was normalized to the mean of the 1962-84 catch per tow and the average at ages $0+1$ and $1+2$ selected as an survey index of relative abundance. The calculated indices are given in Table 14 and summarized in Figure 9. The 1966, 1971 and 1975 are dominant, the 1980 year-class is above average, the 1981 and 1982 below average, and the 1983 year-class the highest since the 1975 year-class. The high $0+$ catch in the 1985 spring survey may also indicate a strong 1985 year-class at age 0 , although results by age group are not yet available.

Comparison of catch per tow in successive years for the same year-class indicates poor correlation for the spring surveys but a higher level for the autumn surveys. It also appears that the 0 -group catch in the autumn survey is indicative of year-class size. Catch of 0 -group fish in the spring survey appears to be inconsistent and may sample only results of occasional early spawning (December) rather than the main spawning in March. Correlation co-efficients for ages 0 to 3 , for the 1975-83 year-classes, are shown in Table 15.

Estimation of Current Stock Status and Fishing Mortality

## Total Mortality Estimates

Calculated values of total mortality ( $Z$ ) and derived estimates of $F$ based on USA spring and autumn survey catch per tow are given in Table 16. Numbers at $4+$ numbers at $5+$ from spring surveys in five time intervals and numbers at $3+/$ numbers at $4+$ from autumn surveys in the same five intervals were used to estimate mortality. Both surveys show an increase between 197780 and 1981-83 and the autumn survey is the higher of the two estimates. The 1981-83 spring survey indicates a $Z$ of 0.74 and the autumn survey 0.98 . However, avallability in the 1982 autumn survey may overestimate $Z$ in the last time period and, as noted above, the spring survey results have not been adjusted for a change in gear. Using the limited time series for 1982-

84 in spring surveys avoids the change in gear used and estimates a 2 of 0.73 and an F of 0.53 .

Additional estimates of $Z$ were derived by taking the mean of the between year values for the same group of cohorts. For spring surveys, the $19834+$ and $19823+$ to the $19845+$ and $19834+$ were used and for the autumn survey the $19813+$ and $19802+$ to the $19845+$ and $19834+$ were included. The spring survey mean was 0.753 and the autumn 0.909 and the geometric mean of both surveys was 0.83 and a derived mean $F$ of 0.63 .

The overall mean estimate of total instantaneous mortality from surveys was calculated to be 0.86 and the resultant $F$ was 0.66 , assuming natural mortality of 0.2.

Sequential Population Analysis (SPA)
Based on resultsg $Z$ estimated from survey data, SPA runs were made with terminal $F$ set to $0.5-0.70$ in 1984. Numbers at age 1-9+ in the catch from 1978-84 were input and $F$ on the oldest age group with incomplete fishing (age 8) set to the mean of ages $3-7$ as was the $F$ on the plus age group. Population numbers at age 3 from each SPA were regressed on autumn numbers at age 2, lagged by one year. The mean $3+F$ from each SPA was regressed on indices of CPUE.

Regression of SPA 3 numbers on autumn survey 2 numbers gave the best overall relationship at an $F$ of 0.6 in 1984 and indicated full recruitment at age three. Correlation between the variables was 0.79 and the 1984 point was close to the predicted value.

Regression of SPA 3+ numbers on autumn survey 2+ numbers, lagged by one year, did not indicate good correlation ( $<0.1$ ) and could not be used to distinguish between SPA runs.

Regression of effective effort (total catch/CPUE) on mean SPA 3+F identified the best overall relationship as total CPUE by USA otter trawlers with $F$ set at 0.6 and correlation of 0.83 .

Regression plots of the numbers and fishing mortality are given in Figures $10-11$. The relationships produced both negative and positive residuals for 1980-83 and it is unlikely that further resolution of terminal $F$ is possible and a value of 0.6 was selected for 1984.

Estimation of Partial Recruitment in 1984
Population numbers at age 1 and fishing mortality from the SPA run with terminal $F$ set at 0.6 in 1984 were used to determine partial recruitment in 1984. Proportion of the maximum observed $F$ for ages 1-6 was determined from the converged part of the $F$ matrix for 1978 -84 and the normalized mean was 0.004 at age $1,0.355$ at age 2 and full recruitment at ages $3+$.

Assuming full recruitment to the survey gear by age one, the catch-atage matrix from the survey was divided into the commercial catch-at age matrix to estimate partial recruitment. The autumn survey indicated a normalized vector of 0.003 at age $1,0.326$ at age $2,0.722$ at age 3 and 1.000 at age 4, while the spring survey indicated $0.049,0.826$ and 1.000 for ages one, two and three. The spring survey can be used in this instance since there is no within year effect of gear changes.

A further calculation was made by estimating size of the 1983 yearclass at age 1 in 1984 from the relation of SPA numbers at age 1 and the survey catch, at age 1. Numbers at age 1 from the SPA run with terminal $F$ set at 0.6 in 1984 regressed on the autumn $0+1$ index predicted 40679 with an R-squared of 0.75 . The autumn catch at: age 0 , lagged by one year, showed poor correlation and could not be used. However, the autumn survey at age 1 , without lag, gave an R-squared of 0.98 and a predicted value of 27521 for the 1983 year-class and can be used since the effect of fishing at age 1 appears to be small. The two estimates were averaged with the geometric mean number at age 1 from SPA for $1978-82$ to obtain a value of 30158 for the 1983 year-class. This value was input in the catch equation to calculate the $F$ required to take the 1984 age 1 catch and the proportion of the fully recruited $F(0.6)$ determined to be 0.005 .

Estimates of the 1982 year-class at age 2 in 1984 were made from the regression of SPA numbers at age 2 and autumn survey at age 1, lagged by one year, with an R-squared of 0.90. Predicted size of the 1982 year-class was 11298. This value was used to calculate the F required to take the 1984 catch-at-age 2 and the proportion of the fully recruited $F$ determined to be 0.226 . Regression plots of the relationships are given in Figures 12-14.

Results of each estimate are given in Table 17 and the geometric mean, normalized to one, gave a vector of $0.007,0.383,0.924,1.000$ 0.742 and 0.759 for ages $1-6$, indicating a dome-shaped recruitment curve. Mean length by age 6 is $>85 \mathrm{~cm}$ and fish of this size may be less aggregated and therefore not as available to the commercial fishery as younger and smaller age-groups. However, full recruitment at age 3 was assumed and the historical recruitment pattern finalized as $0.008,0.415$ and 1 for ages 1, 2 and $3+$.

Partial recruitment in 1984 was estimated from SPA with terminal $F$ set at 0.6. Regression of SPA numbers at age 2 on autumn survey numbers at age 2, lagged by a year, indicated the best overall relationship at a fishing mortality of 0.135 on age 2 in 1984 and a resultant partial recuitment of 0.225 . Similarily, partial recruitment at age 1 was determined from regression of SPA numbers at age 1 on autumn survey numbers at age 1 and gave an $F$ at age one of .004 in 1984 and a partial recruitment of .0062 .

Final SPA Run
Population number, biomass and fishing mortality were calculated from SPA using a fully recruited $F$ in 1984 of 0.6 and a partial recruitment vector of $0.0062,0.225$, and 1 for ages 1,2 and $3+$ in 1984. Results are given in Tables 18 to 23.

Fishing mortality increased from a 3+ mean of 0.400 to a high of 0.609 In 1983 and averaged to 0.584 for 1982-84. Cumulative fishing mortality was above 2.0 for most age groups by 1980. An estimate of partial $F$ for Canadian catches was calculated by division of the percent of the total catch-at-age taken by Canada into the $F$ matrix given in Table 20. Results are given in Table 24 and indicate low fishing mortality for the Canadian catches.

Estimated $1+$ population numbers ranged from 70-80 million from 1978-82 but fell to about 55 million in 1983 and 1984, reflecting the small size of the 1982 year-class at age 1 and 2 . Numbers at age $3+$ were 21 million in 1984, the lowest in the series, but the size of the 1981 year-class is a dominant factor. Similar results are apparent in the estimate of population biomass and the $3+$ biomass was below 90000 t in 1984. This is primarily the effect of high catches of the 1980 year-class at ages 2,3 and 4 as well as low recruitment of the 1981 year-class.

Beginning of year estimates for 1985 were obtained by applying the 1984 fishing mortality and using the 1978-82 geometric mean recruitment of 22600 for the 1984 year-class at age 1 in 1985. Average mean weight at age for 1982-84 was used to calculate biomass. Results are summarized as follows:

Age Group
Population
Number Biomass

| 1 | 22600 | 23707 |
| :--- | ---: | ---: |
| 2 | 19631 | 32568 |
| 3 | 8106 | 19747 |
| 4 | 3702 | 13481 |
| 5 | 3537 | 19139 |
| 6 | 881 | 6014 |
| 7 | 601 | 5420 |
| 8 | 518 | 5100 |
| $9+$ | 374 | 4256 |
|  |  |  |
| $1+$ | 59952 | 129432 |
| $3+$ | 17721 | 73157 |

and indicate further reduction of both $3+$ numbers and 3+ biomass from 1984. However, the $1+$ numbers and biomass remain at about the 1984 level but are dependent on size of the recruiting 1983 and 1984 year-classes. Trends in mean 3+ fishing mortality and 3+ biomass for 1978-84 are shown in Figures 15 and 16.

Yield per Recruit Analysis
Mean weight at age for the combined USA and Canadian commercial catch data for 1982-84 and the mean partial recruitment vector derived from the 1982-84 SPA fishing mortality were used in the Thompson and Bell model.

Input data were as follows:

| Age | Partial Recruitment | Mean Weight |
| :---: | :---: | :---: |
| 1 | 0.016 | 0.936 kg |
| 2 | 0.488 | 1.517 |
| 3 | 1.000 | 2.598 |
| 4 | 1.000 | 3.640 |
| 5 | 1.000 | 5.188 |
| 6 | 1.000 | 6.563 |
| 7 | 1.000 | 8.804 |
| 8 | 1.000 | 10.151 |
| 9 | 1.000 | 11.632 |
| 10 | 1.000 | 14.023 |
| 11 | 1.000 | 16.381 |
| 12 | 1.000 | 19.135 |
| 13 | 1.000 | 22.353 |
| 14 | 1.000 | 26.122 |
| 15 | 1.000 | 30.502 |
| 16 | 1.000 | 35.631 |

Results are summarized in Table 25 and indicate an F 0.1 of 0.150 and an $F \max$ of 0.262 . With a maximum yield per recruit of 1.810 kg and geometric mean recruitment at age one of 22600 thousand fish, the long term yield from this stock is about 41000 t.

The Fishery in 1985
Preliminary Canadian quota reports indicate a catch of 5586 t by otter trawl and 1308 t by longline at the end of August for a total of 6894 t. Catches by small TC 2 and 3 otter trawlers account for 5149 t or about $75 \%$ of the total. No estimates of the USA catch are available at the present time.

A total of 18 samples were collected by Port Technicians, 15 from otter trawl catches and 3 from longliners. Ageing for these samples has not yet been completed, but the estimated catch length frequency of the Canadian catch was calculated and is shown in Figure 17. Fish between $40-55 \mathrm{~cm}$ accounted for about $57 \%$ of the total catch at length and probably indicate strong contribution by the age-groups 2 and 3 and the 1983 yearclass.

Anecdotal information from Port Technicians indicated high catch rates for the TC 2 and 3 vessels and the cod appeared to be well aggregated while feeding on sand lance. A total of 12 samples from these small vessels indicated days fishing per trip ranged between and 1 and 3 days with an average of 2.25 days. Vessels landed between 9 and 36 tons per trip and averaged 24576 kg round weight.

Catch Projection for 1986

No estimates of the total catch in 1985 are available and a value of 40000 t was assumed for illustrative purposes. Mean weight at age and partial recruitment for $1982-84$ were used and a catch of 40000 taken from the 1985 beginning of year population. A fully recruited $F$ of 0.65 was required to take this catch and resulted in a catch in numbers of about 13 million fish of which the 1983 year-class accounted for 38 percent. The 1986 population was then fished at an F0.1 of 0.15 and gave an estimated yield of 10600 t in 1986 . Results of the projection are given in Table 26.

Recent levels of fishing mortality on this stock have exceeded both the FO.1 and Fmax and substantial growth overfishing has occurred. Present stock biomass is at a low level and it is likely that some reduction in fishing mortality will be required to allow stock re-building. Catches from this stock are dependent on the size of recruiting year-classes and the apparent average size of the 1983 and possible below average 1984 year-class will have a substantial impact on catches in 1986.

a. One anomalously larse tow excluded from the calculation,
b. Catch per tow at ase for 1963-69 obtained by applying 1970-81 ase-lensth keys to stratified mean catch per tow at lensth distributions froa each surves,
c. Sprins surveys during 1973-81 were accoaplished with a 'Yankee 41' trawl, In all other sears, sprins surveus were accomplished with a 'Yankee $36^{\circ}$ trawl. No adiustments have been made por these sear differences,
d. Sumer survey in 1978 only szmpled strata $13,16,19-20,23-25$. Sumeer survey in 1981 sampled strata $13,16,19-21,23$ and 25.
e. 1982 survey catches of most species anomalously low (pers, comim, Serchuck).
f. Preliginary

a. Spring surveys, $1973-80$, were accomplished with "41 Yankee" trawl and with "36 Yankee" trawl in other years. No adjustment in catch per tow has been made for these gear differences.
b. Summer surveys only include Strata 13, 16, 19-25
c. Summer survey in 1978 only sampled Strata 13, 16, 19-20, 23-25
d. Summer survey in 1981 only sampled Strata 13, 16, 19-21, 23, 25
e. Excludes one unusually high catch of cod.

Cdn. Preliminary results of Canadian survey in March 1984, Strata 16-22 using a "Western IIA" bottom trawl.
