Biological Stock Update (for 1984) for
American Plaice in NAFO Division 4T

¹This series documents the scientific basis for fisheries management advice in Atlantic Canada. As such, it addresses the issues of the day in the time frames required and the Research Documents it contains are not intended as definitive statements on the subjects addressed but rather as progress reports on ongoing investigations.

Research Documents are produced in the official language in which they are provided to the Secretariat by the author.

¹Cette série documente les bases scientifiques des conseils de gestion des pêches sur la côte atlantique du Canada. Comme telle, elle couvre les problèmes actuels selon les échéanciers voulus et les Documents de recherche qu'elle contient ne doivent pas être considérés comme des énoncés finals sur les sujets traités mais plutôt comme des rapports d'étape sur les études en cours.

Les Documents de recherche sont publiés dans la langue officielle utilisée par les auteurs dans le manuscrit envoyé au secrétariat.

ABSTRACT

An analysis of commercial landings at age with and without discard estimates was conducted. Landings for 1984 were slightly higher than for the previous four years. Research surveys indicate population levels to be similar to levels of the early 1970's. Commercial catch rates calculated from seines, tonnage class 2, (GRT) remained constant from 1977-1983, and decreased in 1984. Abundance indices from research vessel surveys indicate that this stock, despite an observed increase in discards, is able to support a TAC of 10,000 t.

RESUME

Des débarquements commerciaux ont été analysés par âge avec ou sans estimation du nombre de rejets. Les débarquements de 1984 étaient légèrement supérieurs à ceux des quatre années précédentes. Des enquêtes ont indiqué que les populations étaient semblables à celles du début des années 70. Les taux de prises commerciales calculés pour la pêche à la senne en bateau de classe de tonnage 2 (tonnage brut enregistré) n'ont pas varié de 1977 à 1983 et ont diminué en 1984. Les indices d'abondance d'après les relevés de bateaux de recherche indiquent que ce stock, en dépit d'une augmentation observée des rejets à la mer, peut tolérer un TPA de 10 000 t.

INTRODUCTION

The most abundant flatfish in the southern Gulf of St. Lawrence, NAFO Division 4T is American plaice, Hippoglossoides platessoides, (Table 1). Other commercial flatfish species include yellowtail flounder, Limanda ferruginea; witch flounder, Glyptocephalus cynoglossus, winter flounder, Pseudopleuronectes americanus; Greenland halibut, Reinhardtius hippoglossoides; and Atlantic halibut, Hippoglossus hippoglossus.

Flatfish landings in NAFO Divisions 4RST since 1963 have averaged 20,000 t annually, (Fig. 1). Average annual landings from 1975-1980 were approximately 25,000 t. In more recent years (1981-1984) average landings declined to 15,000 t. In 1984, a total of 15,441 t was landed.

The flatfish fisheries, with the exception of the 4RS witch flounder fishery and the inshore 4T winter flounder fishery, are mainly by-catch fisheries to the southern Gulf of St. Lawrence cod fishery. Only 4T plaice and 4RS witch flounder are subject to quota management.

This paper presents a biological update of American plaice in NAFO Division 4T. An extensive review of the biology and stock structure was given in Powles (1965, 1969).

DESCRIPTION OF THE FISHERY

The American plaice is a common subarctic flounder found along the Atlantic coast of North America from Cape Cod to Labrador (Powles 1965). The southern Gulf of St. Lawrence supports an important plaice fishery, as well as a more economically important cod fishery. Since the distributions of cod and plaice overlap during the summer, both species are caught simultaneously and the plaice fishery is often thought of as a by-catch fishery to the 4T-4Vn cod fishery.

Tagging and meristic studies indicate that Magdalen Shallows plaice are a discrete stock made up of two main groups (Powles 1965). The groups are maintained by the tendency of plaice to return to the same areas each summer. The northern or 'Miscou-Magdalen' group includes fish of Chaleur Bay, Shippegan Gully, and Orphan Bank regions. The southern or 'Cape Breton' group occurs from Georges Bay to St. Paul Island (Powles 1965). For management and therefore assessment purposes, these two plaice groups from the Gulf of St. Lawrence are considered as one stock.

Development of the Magdalen Shallows plaice fishery started with the introduction of the first offshore otter trawler in 1947 (Powles 1965). With the introduction and subsequent expansion of the otter trawler fleet, plaice had risen rapidly to commercial importance by the mid 1950's. This is presently an exclusively Canadian fishery made up of a fleet of trawlers, seiners, gillnetters and longliners.

NOMINAL CATCHES

Catches from plaice in NAFO Division 4T between 1972-1983 have averaged 8,380 t (Table 2). These plaice catches obtained from NAFO data, do not include the Unspecified Flounder category (Clay et al 1984). Landings for plaice have in the past included 90 percent of the unspecified flounder

category. This was the conclusion of an analysis by ICNAF in 1973 to analyse the species composition of the unspecified flounder category. Thus plaice landings were then corrected for 1963 to 1971. Powles (1969) also studied research vessel surveys and indicated that American plaice comprised 90% of the flatfish in the northern Magdalen Shallows and 80% in the southern half of the Gulf.

Up to 33% of the landings were taken by otter trawlers (OTB1 and OTB2) in 1984 while seiners (SDN and SSN) took 39%. This was different from the 1983 catch, when 18% was taken by trawlers and 67% by seiners (Clay *et al* 1984). In 1984, gillnet landings were reported as 1,903 t, a four-fold increase over the previous year's catch of 485 t (Table 2).

Trawl catches were concentrated during the summer months in 1983, and again in 1984, especially during August and September (Fig. 2). Seine catches were high throughout the season in 1984, until November. Seine catches in 1983 peaked in June and July. An increase in gillnet landings occurred in August and in September of 1984 (Table 3).

The provisional catch for 1984 was 9442 t. This was an increase of 3105 t since 1983.

AGE COMPOSITION

The commercial catch at age for 1983 and 1984 was constructed from 5,884 fish sampled in 1983 and 7,137 fish in 1984. There were 790 otoliths collected for age determinations in 1983 and 987 in 1984.

The age composition for 1983 was derived by combining the samples by major gear category; trawl, line and gillnet, to obtain three keys for sexes combined. These keys were applied to landings to obtain numbers at age.

In 1984, there were no gillnet samples, and landings for gillnets and other miscellaneous gear were applied to longline samples. This may have caused a bias toward older ages, since longliners usually capture older fish. The growth parameters were obtained from research vessel surveys in 1983 for sexes combined and applied to both 1983 and 1984 keys.

The age composition of plaice for 1984 differs from that of 1983 by the predominance of 11 year old fish. In 1983 there were mostly 11-13 year old fish in the landings. There is some evidence of remnants of the 1972, 1973, and 1974 year-classes passing through the fishery.

The catch at age for 1977-1980 was taken from Metuzals (1981). Catch at age before 1977 was obtained from Schweigert (1978).

RESEARCH VESSEL SURVEYS

Stratified random surveys have been carried out in the Gulf of St. Lawrence, NAFO Division 4T since 1971 during September for all groundfish including plaice.

Mean number per tow and mean weight per tow (Table 4) indicate that the 1984 levels are equivalent to 1982 and to the early 1970's. The mean number

per tow during 1976-1980 indicate high population numbers during that time (Fig. 3). There seems to be a decline in numbers since 1979. The mean weight per tow has followed a similar trend.

Results indicated good recruitment in 1976-1979 when 5+ population numbers were smoothed using the computer function MED3R, developed by G. White (pers. comm.) (Tukey 1977) (Fig. 4). Research vessel population estimates by age and by sex were not available for 1983 and 1984. Estimates from untransformed total numbers of male and female plaice since 1971 indicate a stable population, with high population numbers in 1976-1979 for both males (Table 5) and females (Table 6). Stratified mean catch per tow for sexes combined indicated a high abundance during 1976 and 1977 (Table 7), with a decline since then.

TOTAL MORTALITY ESTIMATES

Total mortality (Z) was calculated using ages 4-8 and 5-9 from the research cruise surveys from 1971-1982. Since the values fluctuated from 1.06 to -0.77, this method of calculation was not considered reliable estimates of mortality (Table 6 and 7).

DISCARDING PRACTICES

A problem with analytical assessments of plaice is the discarding of small unmarketable fish. Accepted market sized plaice are 30 + cm. Various discard studies in the early sixties have been undertaken (Table 8), and estimates of as high as 60 percent by weight (80 percent by number) of plaice discarded have been obtained (Jean 1963). Powles (1969) estimated 21 percent by weight (49 percent by number) from Danish seines in 1961. He found fewer discards and larger sizes of plaice taken by Danish seiners. A D.F.O. unpublished study (1977) estimated plaice and cod discards during the late summer of 1976. Discard rates of 41.9 percent by weight (69.3 percent by number) of plaice were obtained.

Clay et al (1984) described a theoretical change in the pattern of discarding at length, by applying selection ogives to research vessel catch length frequencies. They demonstrated that a larger mean size of plaice was being discarded during the past five years. This increase coincided with a change in mesh regulation, from 120 mm to 130 mm.

Preliminary results from a discard study conducted in 1984 were used to calculate percent discarded at length. This percent at length was then applied to a key obtained from the 1984 research vessel to obtain percent discarded at age.

These results indicate the proposed change in length of discarding did indeed occur. Estimates obtained in 1984 for discards by weight were 39.5 percent (56.1 in number). This is a decrease of 2.4 percent by weight (13.2 in number) when compared to the 1976 study.

CATCH AT AGE

Discards at age were available for 1976, 1980 and 1984. These estimates and prorated values for the intervening years (see below) were applied to the commercial landings-at-age table to obtain a representative catch at age for 1984 (Table 9).

Since estimates for 1979 (unpublished data) and 1980 were taken at the same time as a mesh regulation change (to 120 mm), average discards at age were calculated to apply to the years 1979-1981. From 1981 to 1984, discard estimates from the 1984 study were applied. This estimate in 1984 is applicable for these years since a mesh size of 130 mm regulation occurred (Table 10).

Percent catch at age (with discard estimates) and without discard estimates (landings at age) are presented in Tables 11 and 12. Landings have 10-11 year old fish in 1983 and 1984. There is evidence that more older fish are present in the commercial samples. Using the discard estimates for 1984, it seems likely that there were more 7 year olds in the catch than calculated from port sampling alone.

VPA ANALYSIS

Catch at age, including and excluding discard estimates from 1977-1984, was calculated using VPA in order to obtain stock abundance estimates.

Input parameters were the historical partial recruitment vector (PR) (averaged over 1977-1980) and the weights at age for 1984. Historical partial recruitment was selected as representing the most constant pattern, even though a mesh regulation change occurred in 1981.

AGE:	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21
PR:	.35	.65	.88	1	1	1	1	1	1	1	1	1	1	1	1	1
WT:	.27	.29	.38	.46	.49	.61	.67	.74	.92	1.03	1.16	1.24	1.35	1.32	1.29	1.67

Natural mortality was assumed to be 0.2 for ages 6-21.

These parameters were applied to both numbers-at-age matrices and different terminal F's were tried from 0.1 - 0.5. The VPA analyses were calibrated using exploitable biomass (ages 9-19) and 6+ biomass versus commercial catch rates. The CPUE chosen was the directed catch in hours for plaice by seines, tonnage class 2. The series of resulting terminal F's were examined using the catch matrix including discards (Table 13) and excluding discards (Table 14). Using the criteria of intercept, residuals and correlation coefficient, linear regressions indicated an F_t of 0.4. All regressions of weighted F versus effort were significant, but these were not used in the calibration of the cohort.

Linear regressions of the estimated VPA biomass (1977-1984) obtained from numbers at age including and excluding discards versus research vessel biomass estimates gave a slightly higher correlation coefficient ($r = .75$) with the landings at age (including discards). These results indicate that including discards in a catch matrix may give a better relation to observed research vessel biomass.

The plots in Fig. 5 were calculated by taking the annual biomass estimates obtained from research vessel surveys from 1971-1983 inclusive, and dividing this into the mean biomass. The same calculation was performed on VPA (6+ biomass estimated from VPA using catch at age including discards). Results in Fig. 5 indicate a good relationship of VPA results (1977-1984) with research vessel biomass (1971-1983) for the years 1977 to 1983. The 1984 research vessel biomass estimate was not available. Both biomass estimates (VPA and research) are similar to the commercial catch rates, calculated from directed trips by seines, tonnage class 2. A decline in stock biomass is observed since 1977.

CONCLUSION

Discard estimates have been incorporated into the catch at age from a 1984 study. VPA analyses were performed to obtain exploitable biomass estimates for 1984. Results indicated that a catch at age including discard estimates at age was better correlated with research vessel biomass estimates than a catch at age without discard estimates.

The level of commercial sampling for this stock is inadequate, and the accuracy of the VPA analysis is doubtful. Discarding is also a major problem, and in recent years (1984) discarding by weight is higher than in 1980 but similar to 1976. Discards in terms of numbers, however, have decreased since 1976.

Abundance indices from research vessel surveys (mean numbers and weight per tow) indicate that this stock, with this change in discarding pattern, is able to support a 10,000 t TAC.

ACKNOWLEDGEMENTS

Excellent technical assistance was provided by Ted Currie and Clarence Bourque.
