> Southeast Coast Newfoundland Herring - 1984 Assessment
> by
J. P. Wheeler and E. L. Dalley Fisheries Research Branch Department of Fisheries and Oceans
P. O. Box 5667

St. John's, Newfoundland A1C 5XI

1 This series documents the scientific basis for fisheries management advice in Atlantic Canada. As such, it addresses the issues of the day in the time frames required and the Research Documents it contains are not intended as definitive statements on the subjects addressed but rather as progress reports on ongoing investigations.

Research Documents are produced in the official language in which they are provided to the Secretariat by the author.

1 Cette sērie documente les bases scientifiques des conseils de gestion des pêches sur la côte atlantique du Canada. Comme telle, elle couvre les problèmes actuels selon les ēcheanciers voulus et les Documents de recherche qu'elle contient ne doivent pas être considērës comme des énoncés finals sur les sujets traitës mais plutôt comme des rapports d'étape sur les ētudes en cours.

Les Documents de recherche sont publiés dans la langue officielle utilisée par les auteurs dans le manuscrit envoyē au secrétariat.

#### Abstract

Analysis of data collected in 1984 is presented for the two stock complexes 1) St. Mary's-Placentia Bays and 2) Fortune Bay. Landings from the bait fishery in 1984 amounted to a combined total of 127 t . Samples from this fishery and al so the research gillnet program indicate that the 1979 year-class dominates in St. Mary's-Placentia Bays but the $11+$ group continues to dominate in Fortune Bay. The research purse seine surveys indicate the 1982 year-class to be abundant in St. Mary's-Placentia Bays in 1984 and a predominance of 1982 year-class in Fortune Bay in 1985. Catch rates from the research gillnet program indicated catches were higher in St. Mary's-Placentia Bays but slightly lower in Fortune Bay in 1983. Total mortality coefficients ( $Z$ ) were calculated from the gillnet catch rates but no trends were observed. It was not possible therefore to obtain a best estimate of $F_{t}$ with which to initiate cohort analysis. It was possible, however; to calculate total biomass in Fortune Bay using the age structure of samples and measurements of school size taken during the acoustic purse seine survey and a school size-school weight relationship. Calculation of St. Mary's-Placentia Bays biomass was initiated using a north-south cline (southeast and east coast stocks combined) in the size of the 1982 year-class in relation to the 1968 year-class. Trends in biomass; fishing mortality and recruitment were examined.

## Résumé

Une analyse des donnēes recueillies en 1984 est présentēe pour les deux complexes de stocks (1) des baies St. Mary's et Placentia et (2) de la baie Fortune. Les débarquements de la pêche à la boëtte en 1984 s'élevaient à un total combiné de 127 t. Des échantillons de ces derniers ainsi que le programme de recherche sur la pêche aux filets maillants indiquent que la classe d'âge de 1979 domine dans les baies St. Mary's et Placentia, mais que le groupe de 11+ ans continue de dominer dans la baie Fortune. Les recensements des prises à la senne coulissante indiquent que la classe d'âge de 1982 était abondante dans les baies St. Mary's et Placentia en 1984 et que la classe d'âge de 1982 domine dans la baie Fortune en 1985. Les taux de prises du programme de recherche sur la pēche aux filets maillants ont rēvēlé que les prises ont ēté plus nombreuses dans les baies St. Mary's et Placentia, mais un peu moins nombreuses dans la baie Fortune en 1983. Les coefficients de mortalité totale (Z) ont étē calculēs à partir des taux de prises aux filets maillants, mais aucune tendance n'a été observée. Il a donc été impossible d'obtenir une estimation optimale de $F_{t}$ pour effectuer une analyse de cohortes. On a pu toutefois calculer la biomasse totale dans la baie Fortune à partir de la structure d'âges d'échantillons et de mesures de la taille des bancs pendant le recensement à la seine coulissante acoustique ainsi que d'une relation entre la taille et le poids des bancs. Le calcul de la biomasse des baies St. Mary's et Placentia reposait sur un gradient nord-sud (stocks des côtes est et sud-est combinés) dans la taille de la classe d'âge de 1982 par rapport à la classe d'âge de 1968. Les tendances de la biomasse, de la mortalité due à la pêche et du recrutement ont ēté examinées.

## Introduction

1) Description of Fishery:

Landings from the southeast coast Newfoundland herring stocks (Fig. 1) averaged $30,000 \mathrm{t}$ from 1945 to 1950 and declined to an average of 3450 t from 1953 to 1962 (Templeman 1966). In 1968 landings increased to $21,900 \mathrm{t}$ as a result of a purse seine fishery. Since then there has been a general overall decline (Tables 1-2). The purse seine was the main gear type during the early 1970's and was placed under quota regulation in 1973. In 1980 all gear types were placed under regulation with the purse seine fishery closed in 1981 and the ringnet fishery in 1982. The bar seine fishery was closed in Fortune Bay in 1982 and in St. Mary's-Placentia Bays in 1983. With the quota regulation and resulting closure of mobile gears the proportion of gillnet landings has increased to $100 \%$ in recent years. From 1982 to 1984 the comercial gillnet fishery was closed except for fixed gear bait permits and by-catches from the capelin and mackerel fishery.
2) Nominal Catches:

TAC's and landings from the combined Fortune Bay and St. Mary's-Placentia Bays are listed below:

|  | 1977 | 1978 | 1979 | 1980 | 1981 | 1982 | 1983 | 1984 |
| :--- | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
|  |  |  |  |  |  |  |  |  |
| TAC | 4400 | 5000 | 4400 | 2700 | 1400 | 0 | 0 | 0 |
| Catch | 3847 | 3626 | 4812 | 1918 | 702 | 67 | 55 | 127 |

Input Data

1) Stock Delineation:

As in past assessments the stock complexes considered here are:

1) St. Mary's-Placentia Bays, Areas G\&H (3Lg and 3PSc) and 2) Fortune Bay, Area I (3PSn) (Fig. 1).
2) Biological Sampling:

Although there has been a reduction in commercial catch in recent years, the trend towards increased sampling continued in 1984 (Table 3). This is a result of 1) the experimental gillnet progran which began in 1982,2 ) to a lesser extent on research purse seine surveys which began in 1983. and 3) to the slight increase in the commercial gillnet catches in 1984.

Commercial catch-at-age data (Tables 4-5) for 1984 were generated by applying age compositions from the appropriate comercial samples to landings. Where no comercial samples were available, catch-at-age data were generated using research samples collected from comercial mesh size ( $21 / 2^{\prime \prime}-23 / 4^{\prime \prime}$ ) gillnets. As in the past the catch matrix has been derived for spring-spawning herring only.
3) Acoustic Purse Seine Surveys:

For the second consecutive year an acoustic purse seine (less than 65') survey has been carried out on the two stock complexes. In 1985 one chartered commercial ringnet vessel and the research vessel MARINUS carried out the survey in Fortune Bay, Placentia Bay and St. Mary's Bay. Approximately 2200 mi of cruise track were covered at a speed of 3-5 knots with continuous monitoring of sounder and sonar. Except for some minor variations this year's cruise track was similar to that carried out in February 1984 (Wheeler and Dalley 1984). Detailed observations were made on 58 schools in Fortune Bay, eight sets (none successful for herring) were made in Placentia Bay and no schools were sighted in St. Mary's Bay. Areas of Placentia Bay where herring were caught in 1984 were unaccessible in 1985 due to ice coverage. The survey design and techniques of data collection and analysis were the same as described for the east coast survey. Detailed analyses were available for Fortune Bay only.
4) 1984 Age Compositions:

Age compositions were available from three types of samples: 1) comercial gillnet fishery; 2) research gillnet fishery; and 3) research purse seine survey. Age compositions of the commercial weighted catch (Fig. 2) indicate that age group 5 ( 1979 year-class) is dominant (a change since 1983 when $11+$ was dominant) in St. Mary's-Placentia Bays. This year-class is second only to the $11+$ group in Fortune Bay. The proportion of fall spawners in the commercial catch has increased from 21.6\% to 53\% in St. Mary's-Placentia Bays and from $28.0 \%$ to $36.9 \%$ in Fortune Bay since 1981. This is largely a result of the relative size of the 1979 year-class.

Age compositions from research gillnets (Fig. 3) were similar to the commercial fishery. In St. Mary's-Placentia Bays the 1979 year-class was dominant but not to the extent as in the commercial fishery. The $11+$ age group is dominant in Fortune Bay with the 1979 year-class second. There is also a relatively large proportion of fall spawners in both areas.

The main point from the age composition of the acoustic purse seine surveys (Fig. 4) is the dominance of the 1982 year-class in St. Mary's-Placentia Bays in 1984 (no purse seine samples were available from St. Mary's-Placentia Bays in 1985) and in Fortune Bay in 1985. In 1984 the 1980 and 1979 year-classes were dominant in research purse seine catches in Fortune Bay.

The 1982 year-class was dominant in the acoustic survey in 1985 whereas the 1980 and 1979 year-classes were dominant in the 1984 survey. No purse seine samples were available from the St. Mary's-Placentia Bays acoustic survey in 1985. However; the 1982 year-class was dominant in the 1984 survey in that area.
5) 1984 Age Specific Weights:

Mean weights at age derived from all samples (both commercial and research) collected from January to June of 1984 are shown in Table 6.
6) Abundance Indices:

The research gillnet program initiated in 1982 was continued for a third consecutive year. In 1984 six southeast coast fishermen (Tables 7-8 and Fig. 1) were contracted to fish a fleet of five gillnets ranging in mesh size from $2^{\prime \prime}$ to $3^{\prime \prime}$, for a period of one month (April to May), to maintain an accurate daily log of catch, and to collect and freeze samples from their catch. Actual catches at age are shown in the appendices.

Total catch from the research gillnet program is shown in Tables 7 and 8. Total catch was higher in three of four locations in St. Mary's-Placentia Bays and lower in one location and higher in the other in Fortune Bay. Total combined catches were up in both stock areas in 1984.

As in 1983 (Wheeler and Dalley 1984) catch per unit effort was examined using 1) the total number of herring caught per fishing day (Tables 9 and 10) and 2) total number of herring caught per days hauled (Tables 11-12). Both of these options yield similar results. Using either of these options the catch rate increased substantially in 1984 in St. Mary's-Placentia Bays (combined) and decreased slightly for Fortune Bay (combined).

## Estimation of Parameters

1) Partial Recruitnent Rates:

Partial recruitnent rates (Table 13) were those used in last year's assessment (Wheeler and Dalley 1984). These were derived to more accurately assess younger age groups and to account for a bait fishery prosecuted entirely by gillnets.
2) Calculation of Total Mortality (Z):

After examination of the catch-at-age data from the research gillnet progran it was decided to calculate Paloheimo (1961) $Z$ 's for ages $3+$ as in most cases it appeared that full recruitment to the research gillnets occurred at age 3 . There was no trend in calculated Z's for 1982-84 for either of the two options (Tables 14-15) and therefore it was impossible to obtain a best estimate of $F_{t}$ with which to fine-tune cohort analysis.
3) Calculation of Stock Biomass from Acoustic Surveys:

From the March 1985 purse seine survey in Fortune Bay it was possible to estimate stock biomass according to the steps outlined in Table 16. A total of 99 schools were observed and an area (length $x$ width) of each school calculated from the depth sounder records. Using the relationship derived in the east coast herring assessment (Wheeler et al. 1985) between area and weight, the weight of each school was calculated. The total tons observed was calculated by summing the weights of all schools observed by both vessels. The estimate of total tons observed was then converted to densities based on the area surveyed as determined from the estimate of distance travelled and cruise track width ( 0.30 km ). The
cruise track width was estimated as the distance covered by a sweep of the sonar as set during the survey. Total biomass $(t)$ within $0-90 \pi$ of the area surveyed was calculated by prorating the density estimates by areal expansion. Since a significant number of schools were observed outside the 90 m contour, the biomass estimates are considered to be conservative.

## Assesment Results

1) Population Numbers at age:

Total population numbers were obtained for Fortune Bay (Table 17) from biomass estimates calculated from the acoustic survey as described above and from the mean weights of fish sampled from the acoustic surveys. These represented the population in March of 1985. To obtain population numbers of the 1982 year-class at age 2 the numbers in March 1985 (age 3) were back-calculated to January 1984. To obtain an estimate of the size of the 1982 year-class at age 2 , relative to that of the 1968 year-class, trial cohort analyses were run until population numbers of the 1982 year-class were obtained that approximated the numbers calculated using results from the purse seine survey. $F_{t}$ used was 0.0062 and the results indicated that the numbers at age of the 1982 year-class were $33 \%$ of the 1968 year-class at age 2.

Similar estimates were not available for St. Mary's-Placentia Bays. Instead the strength of the 1982 year-class for this area was based upon a comparison of the 1982 year-class to the 1968 year-class for the areas acoustically surveyed both along the east coast (Wheeler et al. 1985) and the southeast coast. These comparisons (Table 18) were determined from cohort analysis initiated with the empirical population age structures; back-calculated to the beginning of 1984, as derived from the most recent acoustic survey.

A north-south cline existed in the relationship of the two year-classes for the acoustically surveyed areas; a value of 0.38 was chosen to estimate the 1982 year-class in relation to that of 1968 for St. Mary's-Placentia Bays. Trial runs of cohort analysis were conducted for St. Mary's-Placentia Bays to derive an estimate of $F_{t}(0.0065)$ which when combined with the $P R$ historical pattern provided this relationship (0.38) between the two year-classes and stock size estimates at age for 1984.
2) Trends in Biomass and Fishing Mortality:

In both stock areas $2+$ biomass has increased. In St. Mary's-Placentia Bays the increase is the first since 1972 and is in the order of $63 \%$ (Table 19). In Fortune Bay the increase is the first since 1970 and is in the order of $60 \%$ over 1983 levels (Table 20). In St. Mary's-Placentia Bays the present 2+ biomass is approximately $30 \%$ of maximum historical levels and that in Fortune Bay $17 \%$ of maximum historical levels.

With recruitment of the 1979 year-class, $5+$ biomass remained approximately the same in 1984 as in 1983 in St. Mary's-Placentia Bays and decreased slightly in Fortune Bay.

Fishing mortalities for both areas in 1979 were the highest that they have been since the mid 1970's. They have declined in both areas since then as a result of reduced TAC's and closure of the fishery.
3) Trends in Recruitment:

The 1982 year-class is the most significant one in both areas since 1968. In St. Mary's-Placentia Bays it is approximately $38 \%$ the strength of the 1968 year-class and $33 \%$ the strength of the 1968 year-class in Fortune Bay.

Although the 1979 year-class is significant in the age composition of the commercial and research gillnet samples, from the cohort analysis done it is only $5 \%$ the size of the 1968 year-class at age 5 in St. Mary's-Placentia Bays and $3 \%$ the size of the 1968 year-class at age 5 in Fortune Bay. It should be noted however that in excess of $50 \%$ of this age group is fall spawners and the percentages mentioned above represent spring spawners only.

## Prognoses

1) Catch Projections:

The population vectors, as described above, were projected to 1986 , assuming a catch in 1985 of 800 t for St. Mary's-Placentia Bays and 400 t for Fortune Bay. Recruitment was held constant at a level equal to average recruitment for recent years. The catch projections were performed using two options (Table 21) for partial recruitment: 1) combined purse seine and gillnet fishery (Winters and Moores 1977) and 2) gillnet fishery only (Wheeler and Dalley 1984).

Mean weights at age were those derived from samples collected in 1984 (Table 6); Fo. 1 was assumed to be 0.30 . These projections (Tables 22 and 23) show catches for 1986 of approximately 8500 t for a combined purse seine and gillnet fishery and 5600 t for a gillnet fishery only.
2) Management Implications:

The same management implications apply to southeast coast Newfoundland herring as outlined in the east coast Newfoundland assessment (J. P. Wheeler et a1. 1985.).

## Acknowledgments

We would like to thank all technical staff who were involved in the herring research program and in particular, C. I. Barbour, who retired this year after 35 years of service. Thanks also to senior research technicians, R. Chaulk and M. F. Dawson, and samplers; P. Williams, B. Slaney and J. O'Brien. We would also like to thank M. Hynes for typing the script.
