Status of the Atlantic Salmon of the LaHave River,
Nova Scotia, in 1985 and Forecast of Returns in 1986

#### Abstract

The LaHave River of southwestern Nova Scotia is an Atlantic Ocean coastal stream with Atlantic salmon spawning runs composed of more than eighty percent one-seawinter fish. A salmon development project initiated in 1958 has substantially increased natural production which has been reflected in increased recreational catches.

Spawning escapement estimate for 1985 suggests the egg deposition exceeded the 4.91 million egg requirement by about 169 percent, mainly due to escapement of an additional thousand multi-seawinter salmon. Spawning requirement was exceeded both above and below Morgan Falls.

Returns of combined hatchery-return and wild one-seawinter fish were below expectation, while river escapement of multi-seawinter salmon was higher than expected. The 1985 management plan had a favorable impact on the number of multi-seawinter salmon available for spawning.

Predictions of stock abundance in 1986 were made for several stock components and by different methods. Although the forecast for multi-seawinter fish shows a slight increase over 1985, the apparent weakness in the 1985 one-seawinter run does not augur well. Further, the one-seawinter return to the LaFlave is expected to be 10-20 percent lower than in 1985.

## RESUME

La rivière LaHave dans le sud-ouest de la Nouvelle-Ecosse est un cours d'eau 0 ̂tier de 1'Atlantique, dans lequel ont lieu des migrations de saumon de l'Atlantique durant la période du frai. Les bandes de saumons sont composées à plus de quatre-vingt pour cent de saumons ayant passé un hiver en mer. Un projet de développement des ressources en saumons initié en 1968 a permis d'augmenter substantiellement la production naturelle, et s'est traduit par un accroissement des prises de pêche sportive.

Les estimations de taux de survie du saumon au frai suggèrent que la ponte a depassé d'environ $169 \%$ le nombre requis de 4,91 millions d'oeufs, surtout en raison de la survie d'un millier additionnel de saumons de plusieurs annees en mer. Le frai a dépassé l'abondance requise à la fois en amont et en aval de Morgan Falls.

Les chiffres combinés du produit de la pisciculture et de la pêche du saumon sauvage ayant passé un hiver en mer étaient plus bas, mais le taux de survie du saumon de plusieurs années en mer était plus haut que prêvu. Le plan de gestion de 1985 a eu une incidence favorable sur le nombre de saumons de plusieurs années en mer pouvant frayer.

En 1986, on a fait un calcul théorique de l'abondance des peuplements, pour plusieurs composantes du peuplement et par differentes methodes. Bien que les prévisions relatives au poisson de plusieurs années indiquent une légère augmentation par rapport à 1985, la faiblesse apparente du groupe de 1985 ayant passé un hiver en mer est un résultat peu favorable. De plus, on s'attend à ce que le nombre de saumons d'un an en mer retournant à LaHave soit inférieur de 10 à $20 \%$ au chiffre de 1985.

## INTRODUCTION

Description of the LaHave River drainage and its salmon stocks may be found in Cutting and Gray, MS 1984, and Cutting and Jefferson, MS 1985. Although the stock assessments have been vetted through the ACFF Subcommittee, no recommendations have been made by CAFSAC to the managers, due at least partly to the late timing of the prior assessment activity.

Management measures in 1985 incorporated most of those implemented in the 1984 management plan. Commercial salmon fishermen in both directed and interceptory fisheries accepted compensation in lieu of fishing. The angling season opened two weeks earlier, on May 10 rather than May 24 as in 1983 and 1984, but the July 31 closure date was retained. Anglers were prohibited from retaining fish larger than 62.9 cm . Moreover, the daily creel limit on the LaHave was one fish and released fish weren't counted toward that limit. Water levels were favorable for angling well into July, and anglers were generally pleased with the catch.

This document examines the status of the LaHave salmon stocks as experienced in 1985 and presents data and analyses relevant to that 1985 stock status and to the forecasts for 1986.

## METHODS

## Salmon Landings

Exploitation of LaHave stocks in 1985 occurred in the angling fisheryl, the distant commercial fishery and, minimally, as a by-catch in other fisheries gear (Table 1). The by-catch was prohibited by regulation but upwards of 200 fish may have been harvested in Zone 9 wherein the LaHave River is located.

Angling catch, and angler satisfaction, improved in 1985 over the 1984 level. The appearance of additional large salmon was particularly encouraging. Unfortunately, some anglers expressed their indignation at not being able to retain the large salmon by handling fish roughly during catch and release. Fish passing through the Morgan Falls counting facility in 1985 showed a marked increased in scaling and abrasions, as compared to fish appearances in prior years.

## Biological Characteristics

Biological characteristics of the salmon stock have been obtained by sampling the adults at the Morgan Falls counting facility (Table 2).

[^0]
## (1) Sex Ratios

Fish passing the counting facility are sexed by external examination. Past experience has indicated the need for correction of the sexing data for those fish entering the facility before August l. The correction factors utilized to adjust the females were 1.15 and 0.88 , for M-SW and l-SW fish respectively. (Cutting and Gray, MS 1984).
(2) Size

All fish processed at Morgan Falls are weighed and measured for fork length. These data form the basis for the mean lengths and weights of the wild and hatchery-return components by sea age-class.
(3) Grilse/Salmon Ratios

Sea-age ratios were developed, based on the assumption that fish under 63.0 cm were grilse, i.e., lSW salmon (Table 6). The wild grilse/salmon ratio in 1985 was 2.11:1 compared to the 1973-1983 pooled average of 5.4:1. Hatcheryreturn fish (1973-1984) have a pooled average ratio of 3.85:1. The 1984 and 1985 Management Plans have started shifting the ratio toward the salmon (MSW) component.
(4) Fecundity

Fecundity information for LaHave 1SW fish was collected in 1985. All fecundity information from these and MSW fish ( 53 fish ranging 52.0-95.3 cm FL, Table 5) was used to calculate the fecundity on fork length regression:

$$
\mathrm{FeC}=468.08 \mathrm{e}^{0.0353 \mathrm{FL}}
$$

This regression equation is similar to that for the Saint John River,
Fec $=460.19 \mathrm{e}^{0.03605 \mathrm{FL}}$. Test on the regression coefficients showed no statistical difference ( $t=0.306$ ), meaning the samples came from one population.

## (5) Spawning Requirements

A general spawner target of 2,815 lSW fish and 497 MSW fish was determined for the LaHave River (Cutting and Gray, MS 1984). The 1985 target of lSW and MSW spawners was calculated by reflecting the mean sizes, sex ratios, and grilse/salmon ratio of both wild and hatchery-return fish in the run. The target number was that number required to meet a 2.4 eggs $\cdot \mathrm{m}^{-2}$ deposition level for the $2,046,230 \mathrm{~m}^{2}$ of rearing area.

Egg depositions were calculated using the estimated number of females in the 1SW and MSW sea age-classes multiplied by the fecundity value for the mean fork length. Separate calculations for wild and hatchery-return fish were summed.

## 1985 Escapement Estimates

The counting facility at Morgan Falls monitors fish movements for only the upper main river (Figure 1). Thus, estimates of escapement for the entire basin must be developed by construction. The 1985 escapement for the entire river was estimated by three methods.

Method I used angler exploitation rates for hatchery-return grilse and salmon, trap counts at Morgan Falls, angling catch statistics, and mean angler exploitation rates of wild grilse and salmon. Mean angler exploitation rates for hatchery-return salmon, based on recaptures of grilse and salmon which had been released as tagged hatchery-reared smolts and adjusted upward to account for 30 percent non-reporting, were 29.5 percent for 1 sea-winter compared to 24.7 percent for 2 sea-winter and older hatchery-return salmon. These exploitation rates were also used for wild stocks. Losses due to poaching and other mortalities were assumed to be 200 grilse and 100 salmon.

Method II used tag recapture data collected from grilse and salmon captured, tagged, and released from a trapnet located in the estuary of the LaHave River estuary in 1983 to estimate the proportion of the total LaHave stock represented by production above Morgan Falls. Since trap counts are available at Morgan Falls, estimates of total river escapement could be calculated. However, only a few, wild salmon, hatchery-return salmon and hatchery-return grilse were tagged, so only data from wild grilse were used in the analyses. Recapture rate was adjusted for an estimated 30 percent delayed mortality of tagged fish. From this analysis, 30.3 percent of the total escapement of wild grilse reached headwaters above Morgan Falls. In order to calculate wild salmon escapement, it was assumed that other parts of the LaHave River had the same grilse: salmon ratio as the fish at Morgan Falls. Poaching or losses and other mortalities are assumed the same as in Method I.

Method III for estimating wild escapements utilized data on rearing areas and known wild salmon production from the headwaters upstream from Morgan Falls as a proportion of total river nursery habitat. Egg deposition per $\mathrm{m}^{2}$, juvenile production per rearing unit, and factors affecting survival are assumed to be similar throughout the river.

Prediction of 1986 escapement levels
Counts of MSW and 1SW salmon expected to return to the Morgan Falls counting facility in 1986 have been forecast on the basis of information collected at the facility during 1973-1983. MSW wild returns were estimated by two methods. Method A estimated the MSW returns from the significant correlation between the ISW count in year $t$ and the MSW count in year $t+1$. Method B utilized the estimated mean return rate, measured by the number of MSW fish counted at Morgan Falls from the estimated eggs deposited in 1978 and 1979 (Table 8) applied to the estimated eggs deposited in 1981, to estimate the 1986 MSW returns.

The wild ISW returns were estimated using Method $B$ wherein the ISW mean return rate from the 1978, 1979, 1980 and 1981 estimated egg depositions was applied to the 1982 estimated egg deposition to provide the 1986 1SW returns.

Returns of hatchery-reared lSW and MSW salmon to Morgan Falls were estimated on the basis of mean rates of adult return of the estimated smolt outputs since 1976 when the Mersey Fish Culture Station assuned the LaHave River major stocking responsibility (Table 4).

If average angling conditions and no substantial change in angling season are assuned, an estimate of the 1986 angling catch can be made based on application of the estimated mean angling exploitation rates to the estimated returns of wild and hatchery-reared fish. A second estimate of the lSW angling catch used the significant regression of total ISW rod catch on total ISW count at Morgan Falls.

## RESULTS

## 1985 Egg Deposition Relative to Spawning Requirement

The spawning requirement is based on the quantity of spawning and rearing habitat, on fecundity, on sex ratios, on grilse/salmon ratios (Table 6), and on an assumed minimal egg deposition density of 2.4 eggs $\cdot \mathrm{m}^{-2}$.

The target spawning escapement for 1985 was determined from these data:
LaHave River rearing area $=2,046,230 \mathrm{~m}^{2}$ (Cutting and Gray, MS 1984)
Female salmon
(wild 2SW maiden) mean fork length $=71.1 \mathrm{~cm}$
Female grilse
(wild $15 W$ maiden) mean fork length $=54.5 \mathrm{~cm}$
Salmon sex ratio (wild M:F) $=0.10: 0.90$ (Table 6)
Grilse sex ratio (wild M:F) $=0.69: 0.31$ (Table 6)
Grilse/salmon ratio (wild) $=0.68: 0.32$ (Table 6)
The egg deposition per fish for 1985 is 2,237 eggs, as compared to 1,482 eggs in a calculation based on average stock values for 1973-1983. Thus, the required spawning requirement for the average situation, i.e., 3,312 fish, will necessarily decrease to 2,194 fish for 1985 . At the 1985 wild grilse:salmon ratio, the numbers of grilse and salmon required to meet spawning requirements in 1985 are 1,492 and 702, respectively, for the 4.91 million egg deposition needed for the entire drainage.

The deposition requirement for the area above Morgan Falls is 1.65 million eggs. The egg deposition achieved in 1985 was about 4.26 million eggs, without correction for illicit removals or natural mortalities but with correction for broodstock removals from the Morgan Falls facility.

## 1985 Escapements

A comparison of the catches and counts observed in 1984 with the values forecast may prove useful.

|  | Hatchery retum |  |  |  | Wild |  |  |  | Total |  |  |  |

| River escapenent**:MSN(w) | ) | - | - | - | - |  | - | - | 1088 | 1947 | 1188 | 1017 |

* Preliminary pending final angling catches; lSW retained and MSW, released an additional 240 1SW were released. Improved angling conditions in the river in 1985 may have increased the angling exploitation for lSW fish above average levels. Interestingly enough, of the MSW fish passing through the Morgan Falls facility, 24.3 percent showed signs of having been caught and released. This percentage compares favorably with the 24.7 percent mean angling exploitation rate offered in Table 7.
** Forecasts are made based on presence of a commercial salmon fishery. The fisheries management regulations designed to increase the escapement of MSW fish seem to be effective, relative to the forecasts of MSW fish.

The 1SW and MSW returns in 1985 calculated from Method I are summarized below.

## 1986 Forecast of Catches and Escapements

The count of MSW fish at Morgan Falls for 1986 was estimated by two methods.
Method A utilized the significant regression between wild lSW counts in year $t$ and the wild MSW counts in year $t+1$. That regression; $Y_{\text {MSW }}=10.459+$ $0.2412 \mathrm{X}_{1 \text { SWl }} \mathrm{p}<0.01, r=0.906$, 1973-1985; estimates a 1986 Wild MSW return to Morgan Falls of 334 fish (206-462, 95\% C.L.). This return will be a mixture of 2SW and previous spawner fish. Alternatively a significant regression between wild 1SW counts in year $t$ and the wild 2SW counts in year $t+1 ; Y_{2 S W}=7.4716$ $+0.1842 \mathrm{X}_{1 \mathrm{SW}^{\prime}} \mathrm{p}<0.01, \mathrm{r}=0.836$, 1973-1985; estimates the 1986 2SW count will be $255 \mathrm{fish}^{W}$ (146-362, 95\% C.L.). A similar regression for hatchery-return MSW fish; $\mathrm{Y}_{\mathrm{MSW}}=-8.039+0.276 \mathrm{X}_{1} \mathrm{SW}^{\prime} \mathrm{p}<0.02, r=0.72,1973-1985 \mathrm{~W} / \mathrm{o}$ 1983-84; estimates a 1986 MSW hatchery-return of 20 fish ( $0-109,95 \%$ C.L.).

Method B utilized data in Table 8 for the method of determining egg deposition levels for above Morgan Falls, as has been described. Wild adult returns there can be tabulated according to their proper brood year. Because the 1985 fishing plan increased the spawning escapement of MSW fish, it was felt
preferable to use the mean 1978-1979 return rate, 0.011, multiplied by the estimated 4,862,500 eggs deposited in 1981 to provide an estimate of 535 wild MSW fish in 1986 for the circumstance where commercial and/or angling exploitation of MSW fish is permitted. In that circumstance where the limited fishing regime of 1985 is contined in 1986, use of the return rate from the 1980 egg deposition, i.e., 0.016 percent, would raise the estimated return of wild MSW salmon to 778 fish.

The count of wild lSW fish at Morgan Falls is estimated on a similar basis by Method $B$. The return rate chosen for use is the mean rate observed for the 1978 to 19814 -year period. The weighted mean ( 0.038 percent) estimates a return of 1,307 wild 15W fish from the $3,412,600$ eggs deposited in 1982. A further small number of fish are expected to arise as 3 -year-old smolts from the 1981 eggs.

Returns of hatchery-reared 1SW and MSW salmon to the LaHave River in 1986 were estimated from the rates of return to Morgan Falls observed since 1976 from estimated smolt outputs (Table 4). Return rates have averaged as follows:

| Smolt year-classes | Sea-age-class | Mean \% return | Std. dev. | N |
| :---: | :---: | :---: | :---: | :---: |
| 1976-1984 | ISW | 1.31 | 0.52 | 9 |
| 1976-1981,1983 | MSW | 0.26 | 0.15 | 7 |

Utilization of these rates estimates that 14 MSW fish will appear at Morgan Falls in 1986 from the 5,200 smolts arising from the smolts stocked in 1984 and 1985 above Morgan Falls. Additional hatchery-reared smolts below Morgan Falls ( 960 smolts from 12,000 fish stocked in 1984 and 16,050 smolts [64\% of 29,752] from fish stocked in 1985) are estimated to return 287 (1.29x223) hatchery 1SW fish if their pattern of survival, migration, and removal is similar to that for fish returning above Morgan Falls. ABout 68 lSW fish are estimated at Morgan Falls from the 5,000 smolts in 1985. Smolts in 1984 stocked below Morgan Falls ( 9,600 smolts from 12,000 fish stocked in 1984 and 4,224 smolts from 52,803 stocked in 1983) are estimated to result in a further 45 (36xl.25) MSW fish below.

Presentation of a numerical forecast for the commercial catch of MSW fish in FSD's 26 and 27 is not possible. Although there is a significant correlation between the commercial MSW catch and the lSW count at Morgan Falls in the prior year for 1973-1980, changes in the commercial fishing season and in the statistics reporting have invalidated the regression for the period since 1980.

River escapement of 1,326 ( $1,099-1,600,95 \%$ C.L.) wild MSW fish is forecast on the basis of the $\ln -\ln$ regression of the total MSW returns in year $t+1$ on total lSW returns in year $t$ (Table 9), $\log _{\text {eush }}=-3.60003+1.31172$ $\mathrm{Log}_{\mathrm{e}_{15 G^{\prime}} \mathrm{r}=0.926 \text {, } \mathrm{n}=12,1973-1985, \mathrm{p}=0.00001 \text { ( } \mathrm{Y} \text { converted from geometric } \mathrm{c}}$ mean ${ }^{2} W^{\prime}$ arithmetic mean per Ricker, 1975, p. 274-275).

Estimation of the 1SW angling catch in 1986 was determined from the regression of the total lSW ( $\mathrm{HR}+\mathrm{W}$ ) angling count on total lSW (HR +W ) counts at Morgan Falls in the same year. This regression; $\mathrm{Y}_{\mathrm{ROD}}=445.94+$ $0.4222 \mathrm{X}_{\mathrm{MF}^{\prime}} \mathrm{r}=0.66, \mathrm{n}=13,1972-1985, \mathrm{p}<0.02$; estimates a 1 SW rod catch of

1,026 (706-1,346, 95\% C.L.) in 1986 from the estimated 1,375 1SV fish count forecast for Morgan Falls. Attainment of that catch (which is based on C\&P statistics) will depend on average fishing effort in 1986 and on suitable climatic conditions for successful angling.

In summary, the numbers of LaHave fish counts and harvests estimated for 1986 are:

1986 Summary Forecast
1-SW M-SW

| 1-SW | M-SW |  |  |
| :---: | :---: | :---: | :---: |
| River escapement <br> (W) 6.289 million eggs $x$ $0.038 \% \times 1.29$ (for angling correction) <br> (H) $(68+223) 1.29$ | 1,326 $(14+45) 1.25$ | 3,458 | 1,326 |

## Discussion

The egg requirement for the area above Morgan Falls is 1.65 million, at a deposition rate of 2.4 eggs $\cdot \mathrm{m}^{-2}$. The threshhold has been exceeded beginning with 1978 (Table 8). The rates of adult return to Morgan Falls continue to decrease as the egg deposition has increased. Because the egg deposition which will provide the 1986 lSW returns was less that that for the 1985 returns, it will now prove interesting to see if the return rate in 1986 shows improvement over the lowest 0.028 percent rate seen in 1985.

The three methods of estimating the adequacy of the spawning escapement in 1985 suggest egg depositions continue to be more than sufficient (Table 9). The estimates are very sensitive to the angling exploitation rates utilized. These rates, in turn, rely on reasonably accurate angling catch estimates. The angling fishery in 1985 was unusual because suitable water conditions lasted almost the whole season, good numbers of fish came into the river, and some released fish
weren't counted against the bag limit. The different regulation regarding release of fish seems to have resulted in unusual impact on angling statistics. In the case of grilse, better anglers sometimes released smaller grilse in expectation that a larger grilse could be caught. In the case of the salmon, riverbank "talk" and observations strongly suggested some anglers were enhancing their alleged prowess by claiming to have released fish which were just pricked, or which were fought only briefly, or which were escaped grilse that were "willed" to have been salmon. If this attitude carried over onto the license stub returns, then the alleged salmon catch is substantially overstated. Two sources of information suggest the MSW salmon run was not inordinately large nor was the actual catch rate of salmon unusual. The salmon run to Morgan Falls was such that addition of the 1985 count to the regression of MSW count on ISW count in the prior year improved the regression coefficient; thus the run was not outside the variation already documented. Second, the fish passing Morgan Falls were examined for evidence of having been caught by angling. Fish with evidence fell mainly into two groups, those with an obvious hook injury and with some scaling and those showing scaling only-a condition not seen in prior years. The percentages of the fish showing these evidences add to 24.3 percent, which compares quite well with the 24.7 percent angling rate derived from the tag returns (Table 7). In the case of the lSW fish, examination of the Morgan Falls fish showed 6.9 percent had apparently been handled. Assuming a 29.5 percent angling exploitation rate for 1SW fish, the 6.9 percent translates to a release rate of 14.2 percent. The latter compares well with the 12.55 percent release rate reported in the first 38 percent of the license stub returns for the LaHave. The small difference can be because of inclusion of "jigged" fish in the count or because the relative production of lSW fish is better above Morgan Falls than below Morgan Falls. combining the caught and released components suggests a lSW angling "exploitation" rate of 34.4 percent in 1985.

In summary, the river escapements of 1 SW and MSW fish are not expected to exceed those occurring in 1985, with or without the commercial fishing option.

 Table 7
Thus: Fishway count HR Grilse - Fishway counts HR Grilse = number of HR Grilse angled

Total annual angling catch of grilse minus Column $1=$ Column 3 (wild grilse). Total annual angling catch of salmon minus Colum $2=$ Column 4 (wild
 return statistics.
3. Fish trap count at Morgan Falls
4. Based on angling exploitations at 0.295 (1SW) and 0.247 (MSW) divided into angling catch $=$ river escapement.
5. Total river escapement of grilse $=$ Colum $1+5+9=$ Colum 11; total river escapement of salmon $=0$ olumn $2+6+10=$ Column 12 (See footnote 12 )
6. Low water conditions in July, Aug., and Sept. adversely influenced ISW angling catch but not MSW salmon catch in June.
7. Failure of the 1977 smolt year-class; low water conditions in June, July, Aug., Sept. adversely influenced ISW and MsW angling catches in 1978.
8. Failure of the 1977 smolt year-class adversely affected the MSW returns in 1979.
9. Estimated from regression $Y_{M F}$ count $15 W=1.98 \mathrm{X}_{15 W}$ angling-849.72 (1973-'77, 1979-'82), minus HR grilse in Column 1 , $\div 0.295$.
10. Estimated from mean ratios of grilse (time t) to salmon ( $\mathrm{t}+1$ ) (1973-1982) of 3.121G:1S.
11. Egg deposition : Grilse (Colums 14 and 16) and Salmon (Colums 15 and 17); annual mean fork length in Fec. $=468.08 e^{0.0353 F L}$ times $\% \mathrm{~F}$ times no. of fish.
Estimated deposition from broodstock collections has been removed. No adjustment for instream losses to poaching or mortalities. Morgan Falls counts determine numbers of spawners there. Lower basin grilse = Colums $11-(1+3+5+7)$. Lower basin salmon $=$ Colums $12-(2+4+6+8)$.
 groups stocked above Morgan Falls.
13. Angled MSN fish were released for spawning with 10 percent mortality.

Fig. 1. The LaHave River drainage, Nova Scotia.

[^0]:    1 Angling catches are available from two sources; the Conservation and Protection Branch, DFO, which is the traditional one, and the new license stub return system which is a cooperative project between DFO and the N.S. Dept. Lands and Forests. This assessment uses mainly the long-term data base available from the former source.

[^1]:    * Data are adjusted to reflect freshwater age composition of the returns.
