## SUBDIVISION 4Vn COD (MAY - DECEMBER): STATUS REVIEW FOR THE 1985 FISHING YEAR

by

S.J. Smith and A.F. Sinclair<br>Marine Fish Division<br>Department of Fisheries and Oceans<br>P.0. Box 1006<br>Dartmouth, Nova Scotia<br>B2Y 4A2

1
This series documents the scientific basis for fisheries management advice in Atlantic Canada. As such, it addresses the issues of the day in the time frames required and the Research Documents it contains are not intended as definitive statements on the subjects addressed but rather as progress reports on ongoing investigations.

Research Documents are produced in the official language in which they are provided to the Secretariat by the author.

1 Cette sērie documente les bases scientifiques des conseils de gestion des pêches sur la côte atlantique du Canada. Comme telle, elle couvre les problèmes actuels selon les échēanciers voulus et les Documents de recherche qu'elle contient ne doivent pas être considérés comme des énoncēs finals sur les sujets traitēs mais plutôt comme des rapports d'ētape sur les études en cours.

Les Documents de recherche sont publiēs dans la langue officielle utilisée par les auteurs dans le manuscrit envoyē au secrētariat.

#### Abstract

Nominal catch of cod in 4 Vn (May-December) was $12,366 \mathrm{t}$ in 1985, an increase of 1839 t from 1984. All gear categories with the exception of longlines shared in the increase. The longline catch remained much the same as last year. Age information was available from most major gears for the second year in a row allowing for some preliminary comparisons between gears. A short-term forecasting method for estimating the projected catch for 1986 was applied to this age information. The method which assumes that fishing mortality in 1986 will be equal to the fishing mortality in 1984, resulted in an estimated catch biomass for 1986 of $10,700 \mathrm{t}$. This estimate, although based on different assumptions than the general production model used in the past, was comparable to past estimates of the long term yield from the latter method. However, total mortality estimates imply that fishing mortality has been in excess of $F_{0.1}$ and the estimated catch at $F_{0.1}$ was estimated to be $6,100 \mathrm{t}$.

## RESUME

Les prises nominales de morue dans la division $4 V n$ (mai à décembre) ont été de 12366 t en 1985, soit une augmentation de 1839 t par rapport à 1984. Toutes les catēgories d'engin de pêche, à l'exception de la palangre, ont connu une augmentation de prises. Dans le cas de cet engin, les prises sont demeurées sensiblement les mêmes que l'annēe dernière. Les donnēes sur l'âge disponibles pour deux annēes consécutives et pour la plupart des engins nous permettent d'établir certaines comparaisons prēliminaires. On a appliqué à ces donnēes sur l'âge une méthode de prévision à court terme pour ēvaluer les prises prévues pour 1986. La méthode, qui suppose que la mortalité due à la pêche en 1986 sera égale à celle de 1984, a permis d'établir à 10700 t la biomasse des prises prēvue pour 1986. Bien qu'elle s'appuie sur des hypothèses autres que le Modèle de production gēnéralisēe utilisé par le passē, cette estimation se compare aux estimations du rendement à long terme ētablies antérieurement par cette méthode. Cependant, les estimations de la mortalité totale laissent supposer que la mortalité due à la pēche a dépassē la valeur $\mathrm{F}_{0.1}$ et les prises projetēes à ce niveau ont ēté fixēes à 6100 t .

## Introduction

Previous advice on this stock has been based on the apparent strengths of incoming year-classes to the fishery from research surveys and the results of a general production model analysis. The general production model was fitted to total catch and an effort series derived from stratified mean weight caught per tow estimates. The calculated $2 / 3 \mathrm{E}_{\mathrm{MSY}}$ yield for the 1984 and 1985 assessments were $10,200 \mathrm{t}$ and $10,500 \mathrm{t}$ respectively. The TAC for 1985 was $12,000 \mathrm{t}$. Total mortality estimates from the survey data and longline catch-per-unit-effort at age have indicated that fishing mortalities in recent years have exceeded $\mathrm{F}_{0.1}=0.2$.

The nature of the fishery has been changing over the last five years. In 1980 and 1981 the longliner component predominated over the otter trawlers. In the last three years otter trawlers particularly tonnage class 2 and 3 vessels have become a major part of this fishery.Catches of these vessels have been increasing in recent years while the longline catch has dropped to about half of the 1981 level. The Assistant Deputy Minister (AFS) has requested that CAFSAC investigate these trends and try to determine how they are related. Some preliminary results are presented here.

## Nominal Catch

The nominal catches by country for the period 1970-1985 are presented in Table 1 and plotted in Figure 1. The only foreign catch reported for 1985 was the small bycatch from the Japanese redfish fishery. Total landings for 1985 were up by 1839 t over the previous year. This increase was realized by all major gears with the exception of the longliners whose catch decreased marginally from the previous year (Table 2). The percent composition of catch by gear over the period 1970-1985 is presented in Figure 2. Note the recent increase in percent catch on the part of the otter trawls.

Landings by gear and tonnage class are presented for 1984 and 1985 in Table 3. Tonnage class 1 otter trawlers are all but gone from the fishery while the other tonnage classes continue to increase their share of the landings. The tonnage class 3 vessels continue to be the major part of this gear component. For longliners, only the tonnage class 1 vessels showed an increase in catch.

The monthly breakdown of landings by gear component given in Tables $4 a$ and $4 b$ show a change in pattern for the longliners. Previously landings for this fishery started out high in May, then decreased over the summer and then increased again in the fall. Many of these boats would participate in the crab fishery in the summer months. In 1985 longliner landings peaked in the summer instead. The abrupt drop in the otter trawl landings after August was due to the closure of this fishery effective August 23. The temporal trends for the handines and seines are similar to those of previous years.

## Research Surveys

Estimates of mean numbers/tow by age and estimated total numbers/tow and weight/tow from the summer research surveys for 1970 1985 are presented in Table 5. Variance estimates are not included here but planned modifications to STRAP and other software used for this assessment will make it possible to provide them in the future. Note that the estimates given in Table 5 are arithmetic averages.

The 1985 mean catch/tow for both numbers and weights are the highest recorded for this survey. The bulk of this estimate was made up of 5 year olds ( 1980 year-class) although the mean/tows for ages 6, 7, and 8 are also relatively high for those ages. In Table 6 the stratum means (numbers) are given for 1970-1985. The means for strata 40 and 41 are in line with previous results, however the mean in stratum 42 is well beyond any previous values. There was one large set in stratum 42 containing 1460 cod, $55 \%$ of which were 5 year olds, $22 \%$ and $9 \%$ were 6 year olds and 7 year olds respectively. These percentages of fairly old fish in this stratum are unusual. In the past there has been a general trend of year-classes moving to deeper waters as they grow older (Smith and Sinclair, MS1985). Stratum 42 is the shallowest stratum of the three in 4 Vn . Catches in stratum 41 were also dominated by 5 year olds. Comparison of age-length keys from the 1983, 1984 and 1985 surveys indicate that fish of the 1980 year-class appear smaller in size than previous year-classes at the same age. Lengths for age 5 fish had generally ranged from 43 cm . to 63 cm . with a peak around $52-55 \mathrm{~cm}$. The 1980 year-class fish range from 34 cm . to 58 cm . with a peak at 46-49 cm.. Lengths at age from the commercial samples were similar. The department's port sampler in Sydney has commented to us about the smaller size of these fish and reported that the fisherman had also noted this phenomena. Obviously more investigation has to be carried out on this apparent trend.

## Commercial Catch at Age

Sampling coverage of the commercial catch was good for 1985 with most major gears being adequately covered. However, only two samples were reported for tonnage class 2 longliners and these were collected in the fall. There were no handline samples collected. The data used to generate the age-length keys are summarized in Table 7. In order to maximize the age information available, all otoliths were used regardless of the gear the samples were taken from to convert the length frequencies to age compositions. Both age and length samples were separated into two time periods; May-September and October-December. The length-weight parameters were obtained from analysis of the 1985 groundfish survey data.

The longliner catch at age remains the only longterm time series of data reflecting the age composition of this stock. However we now have two years of information for otter trawlers and seines. The longliner series is presented in Table 8 and average weight at age for this gear is presented in Table 9. The longliners continue to concentrate on the older year-classes particularly the 1977, 1978 and 1979 year-classes. Note that the 1980 year-class was also a significant proportion of the catch.

Catch at age for the otter trawls and seines are presented in Table 10 along with their 1984 estimates. The catch at age for longliners, otter trawls and seines are presented in Figure 3. The available catch-at-age information indicated that the longliners concentrated on $7,6,5$ and 8 year olds in that order (mean $=7.2$ years) while the otter trawls mainly caught 5,7 and 6 year olds (mean= 6.3 years).

Catch per Unit Effort
The CPUE estimates for longliner tonnage class 2 vessels for 1968 to 1985 are given in Table 11. The trend in longliner effort is presented in Figure 4 for the period 1980-1985. Note the increase in effort over last year while catch (Table 2) has remained fairly stable.

## Mortality Estimates

Total mortality estimates were calculated from CPUE (numbers) at age for the longline catch for 1980-1985 (Table 12). Although there is a great deal of variability between years the mean estimates indicate a leveling off of mortality levels at age 8 which appears to be consistent with the recruitment pattern for this type of gear. Assuming that natural mortality is 0.2 the total mortality estimates for age $8+$ indicate a fishing mortality in excess of 0.4 which is twice $F_{0.1}=0.2$.

Estimates of mortality from the survey data were not included here because the high catches in the survey this year gave negative estimates of mortality for most age groups.

Total mortality was also calculated from a catch curve obtained from a multiplicative analysis of longliner catch at age for the same time period. The methodology is sumarized in the report of the 1985 ICES Working Group on Methods of Fish Stock Assessments (Anon. 1986). The model expresses catch at age as a multiplicative function of year, age, and year-class effects. The output includes a catch curve (age effects) corrected for variations in estimated year-class sizes. The resulting catch curve indicates full recruitment to the gear at age 6 (Figure 5). A regression through ages 6-12 indicates total mortality of 0.61 . Assuming natural mortality of 0.2 this indicates fishing mortality of 0.41 .

Interaction between Longlines and Otter Trawls
In a memo received from the Chairman of the Groundfish Subcommittee we were directed to give advice on the possible effect of the annual transfer of quota from the small fixed gear fishery to the small mobile gear fishery in 4 Vn . This practice has been occurring since 1981 . It was suggested that this practice may have contributed to the decrease experienced by the small fixed gear fishery.

The allocation history of this fishery is presented in Table 13. The sources for this material are the Department's Quota reports and Groundfish management plans. The final catches given in the table are taken from the Dec. 31 Quota reports. TAC's for the management unit were increased in mid-season in 1981 and 1982. The fixed gear component
(<65') exceeded it's quota in 1981 despite the mid-season increase. Since then the small fixed gear fleet has not reached it's quota. Beginning in 1983 the mobile gear ( $655^{\prime}$ ) fleet has consistently exceeded its quota despite large transfers from the fixed gear ( $<65^{\circ}$ ) fleet. These were both initial and mid-season transfers. Thus the fixed gear ( $665^{\prime}$ ) fleet has experienced both absolute and proportional decreases in it's allocation. On the other hand the quota and catch for the small mobile fleet has increased and thus it is exerting proportionally higher fishing mortalities than it had in the past. Generally, otter trawlers concentrate on younger fish than the longliners do (Table 10 and Fig. 3) and possibly reduce the stock before they are old enough for the longliners to take full advantage of them.

Unfortunately we have only two years of data on age composition to compare and therefore can say very little about past trends. Comparison of total mortality estimates in Table 14 offers little assistance. The estimates for the otter trawls appear to be unrealistically low since all but one are below 0.2 . For longliners the estimates indicate high fishing mortalities. Little is known about the temporal/spatial distributions of these gear categories and at this time little can be said about how they may be competing. Therefore any formal advice on this question will have to wait for the collection of more age composition data and the analysis of any positional and seasonal information we may have on hand. Further data collection may be warranted for the latter investigation.

## Estimation of Total Allowable Catch

Previous advice on setting catch levels for this stock were partly based on results from a general production analysis of total catch and an effort series derived from survey mean weight per tow. The large mean weight per tow for 1985 would correspond to a drop in effort in 1985 contrary to indications given by the catch rates from the longliners and otter trawls. Therefore the general production model may provide an erroneous view of the status of this stock and because of this an alternate approach was applied here.

The lack of catch at age information for this stock has always hampered efforts to carry out an analytical assessment. In the last two years efforts have been made to rectify this situation. Given that we now have two years of reasonably complete age composition data for the major gears in this fishery the opportunity arises to use one of the short-term forecasting methods currently popular in ICES. The method chosen for use here is known as the Leap-Frog TAC (Pope, 1983). This method assumes that we have two years of data for year $t$ and $t-1$ and wish to estimate the projected catch for year $t+1$. Assuming that $F_{t}=$ $F_{t-1}$ we can estimate the catch, $C$, in year $t+1$ at age $j+1$ by,

$$
C_{t+1, j+1}=\frac{C_{t_{, j+1}} C_{t j}}{C_{t-1, j}}\left(\frac{F_{t-1}}{F_{t}}\right)^{2}
$$

The basic requirements for this method are catch at age for the two years, an estimate of recruitment for the youngest age in the fishery
for year $t+1$, average weight at age over the two years and a measure of the relative change in $F$ from year $t-1$ to year $t$. Pope suggests using the ratio of effort for these two years if constant catchability can be assumed.

The catch at age for 1984 and 1985 was constructed from the basic data given in Table 10 . The total catch at age for all gears was estimated by prorating the catch for available gears to the total landings given in Table 1. The results are presented in Table 15. The average weight over the two years 1984 and 1985 was also calculated from the commercial age and length samples. Effort is available for longliners and tonnage class 2 and 3 otter trawlers. Total effort for each year was calculated for each of these gears and then combined by using the coefficients obtained from the multiplicative analysis for the 4VsW cod assessment. These coefficients were used to express the effort units of the longliners and tonnage class 2 otter trawlers in the same scale as the tonnage class 3 otter trawlers. The recruitment to age 3 was estimated from the average catch at age 3 from 1984 and 1985. The TAC was estimated following Pope's formula as,

$$
T A C=\sum_{j=3}^{16} W_{j} C_{i+1, j} .
$$

The estimated catch of $10,710 \mathrm{t}$ falls within values suggested in the past by the general production model and indeed appears reasonable given the recent history of this stock. Since the method also provides us with a projected catch at age we will be able to evaluate the potential usefulness of this method next year. For the moment given the paucity of data on age composition this method is the best we have.

An alternative approach which uses information from the total mortality estimates was carried out as follows. The estimated fishing mortality on this stock is approximately twice $\mathrm{F}_{0.1}$. Abundance indices from both research surveys and commercial catch rates indicate relative stability in the population in the last 6 years. The average catch over the same period has been $11,200 \mathrm{t}$. Using the catch equations the biomass (B) may be estimated as,

$$
\begin{aligned}
\hat{B} & =\frac{C Z}{F\left(1-e^{-2}\right)} \\
& =37,235
\end{aligned}
$$

where,

$$
C=\text { average catch }(11,200, t)
$$ $Z=$ current total mortality (0.6) $\mathrm{F}=$ current fishing mortality (0.4)

Therefore one could estimate the $F_{0.1}$ catch as

$$
\begin{aligned}
\hat{\mathrm{C}} & =\frac{F_{0.1}}{Z_{0.1}} \hat{B}\left(1-e^{-Z_{0.1}}\right) \\
& =6138 \mathrm{t}
\end{aligned}
$$

This estimate is made with the assumptions that biomass has been relatively stable in the recent past, age structure is stable, recruitment has been stable and there has been no changes in partial recruitment.

## Summary

Abundance indices from the research surveys indicate higher than usual levels for this stock. The 1980 year-class predominates but older year-classes remain relatively abundant. This year was unusual in that older fish than is usually expected were caught in the shallow stratum (42).

Commercial catch per unit effort from longliners decreased from the 1984 level. The number of records that this is based on remains small.

This is the second year in which the major gears have been sampled for length and age. This year it appears that although the otter trawlers were catching substantial numbers of 5 year olds they also were concentrating on the older fish much like the longliners. Monitoring of sampling will continue in order to ensure that all major gears continue to be covered.

For the moment little can be said about the effect of the annual transfers of quota from the small fixed gear component to the small mobile component of this fishery. Further research must be done on the temporal and spatial distributions of these vessels and more age composition data must be collected.

Given that we now have two years of age composition information a semi-analytical assessment was attempted. The Leap-Frog TAC method was applied to this information and resulted in a projected catch of $10,710 \mathrm{t}$ for 1986 which is line with previous advice based on a general production analysis. This method provides an estimated catch at age for 1986 and therefore will be validated once the 1986 information is analyzed.

Both the $2 / 3 E_{\text {msy }}$ obtained from past analysis using a general production model and the projected catch from the Leap-Frog method appear to reflect exploitation of the stock at high fishing mortality rates. Total mortality estimates over the last five years continue to indicate that fishing mortality has been in excess of $\mathrm{F}_{0.1}=0.2$. The $F_{0.1}$ catch is estimated to be $6,100 \mathrm{t}$.

| 14 | 5 | 5 | 5 | 10.23 |
| 15 | 6 | 6 | 4 | 8.62 |
| 16 | 9 | 8 | 5 | 13.20 |

$T A C=10,710(t)$

$$
\left(\frac{F_{84}}{F_{85}}\right)^{2}=\left(\frac{f_{84}}{f_{85}}\right)^{2}=0.686
$$

* Recruitment was estimated from average age 3 from 1984 and 1985.

Figure 5. Catch curve for $4 V n(M-D)$ cod estimated from longliner catch at age 1980-85. For ages 6-12 total mortality was estimated to be 0.61 using linear regression.

[^0]:    * Initially set at 7500 t, Increased in September to 10,000 t.
    ** Initiaily set at 10500 t. Increased November 1 to 14,000 t.
