Capelin in NAFO SA2 + Div. 3 K
by
J. Carscadden and D. B. Atkinson

Science Branch
Department of Fisheries and Oceans
P. O. Box 5667

St. John's, Newfoundland AIC 5X1

1 This series documents the scientific basis for fisheries management advice in Atlantic Canada. As such, it addresses the issues of the day in the time frames required and the Research Documents it contains are not intended as definitive statements on the subjects addressed but rather as progress reports on ongoing investigations.

Research Documents are produced in the official language in which they are provided to the Secretariat by the author.

1 Cette sērie documente les bases scientifiques des conseils de gestion des pêches sur la côte atlantique du Canada. Comme telle, elle couvre les problèmes actuels selon les échéanciers voulus et les Documents de recherche qu'elle contient ne doivent pas être considérēs comme des énoncēs finals sur les sujets traités mais plutôt comme des rapports d'ētape sur les ētudes en cours.

Les Documents de recherche sont publiés dans la langue officielle utilisée par les auteurs dans le manuscrit envoyé au secrētariat.

## Abstract

This paper summarizes data from offshore research activities and from the comnercial offshore fishery for capelin in NAFO SA2 + Div. 3K. A comparison of distribution and timing of the commercial capelin fishery and the Canadian acoustic surveys for capelin indicated that the surveys are conducted at a time appropriate to estimate capelin abundance. Capelin age compositions from the Canadian surveys generally exhibit higher proportions of younger fish than age compositions from the commercial fishery probably because of the fine-mesh liner in the survey gear. In most years, Soviet fishery samples and Canadian research samples agreed in the identification of the relative strengths of year-classes. A comparison between the Canadian acoustic surveys for capelin and distribution of capelin taken during groundfish surveys indicated that the acoustic coverage of strata containing capelin during the groundfish survey was generally good in Div. 2 J but not so complete in Div. 3K.

Commercial catch rates from different sources showed a similar pattern since 1977 when the dominant gear has been TC7 USSR midwater trawlers. There was a decline through the late 1970's and then a general increase since then. Concern has been expressed about the comparability of commercial catch rates between recent years and earlier years in the series.

Catch rates of capelin from groundfish sets exhibited different trends depending on the treatment of the data. Because the groundfish surveys are not designed to sample pelagic, schooling fish that exhibit diel migrations these catch rates may not be suitable as abundance indices but may be useful to describe the distribution of capelin.

USSR acoustic estimates were available from 1974-84 (except for 1981) and the trends of this series and commercial catch rates were similar. Canadian acoustic estimates were available only for 1981-85 (except for 1982). The trend of this series was different from the commercial catch rate series but more similar to the catch rates of capelin from the groundfish surveys.

## RESUME

Le prēsent document rēsume les donnēes sur les activitēs de recherche et de pēche hauturières pour le capelan dans la sous-zone 2 et la division 3 K de l'OPANO. Une comparaison entre, d'une part, la distribution et la période de pêche commerciale du capelan et, d'autre part, les relevēs acoustiques canadiens du capelan a rēvēlē que ceux-ci sont menēs à un moment appropriē pour
l'estimation de l'abondance de l'espèce. Les compositions selon l'âge tirées de relevēs canadiens montrent en gēnēral des proportions plus èlevēes de jeunes poissons que les compositions selon l'âge obtenues de la pêche commerciale; ceci est probablement dû à l'utilisation d'un maillage fin dans les engins de relevē. Pour la plupart des annēes, les échantillons prēlevēs dans les captures russes et les èchantillons canadiens expërimentaux concordaient pour ce qui est de l'établissement des tailles relatives des classes d'âge. Une comparaison entre les relevēs acoustiques canadiens du capelan et la distribution de l'espèce observēe au cours de relevēs du poisson de fond a rēvēlē que la couverture acoustique des couches habitées par le capelan au cours de ces derniers relevēs étaient gēnéralement bonne dans la division 2 J , mais pas aussi complète dans la division 3K.

Les taux de capture commerciale obtenus de diverses sources montrent une tendance semblable depuis 1977 dans les cas où le principal engin utilisē ētait le chalut mēso-pēlagique russe (CJ7). Le dēclin observé vers la fin des annēes 1970 a ētē suivi d'un accroissement général. On s'est intēressē à la comparabilité des taux de capture commerciale observēs ces dernières annēes et de ceux obtenus les annēes précēdentes.

Les taux de capture du capelan dans les coups de filet pour le poisson de fond ont montrē diffërentes tendances selon le traitement des donnēes. Etant donné que les relevēs du poisson de fond ne sont pas conçus pour l'ēchantillonnage des poissons pēlagiques en bancs qui effectuent des migrations nycthémérales, ces taux peuvent ne pas être adéquats comme indices d'abondance mais peuvent servir à la description de la répartition du capelan.

Des données acoustiques recueillies par l'URSS ētaient disponibles pour la périod 1974-1984 (sauf 1981); les tendances de cette sērie et des taux de capture commerciale étaient semblables. Les estimations acoustiques canadiennes ne couvraient que la pēriode 1981-1985 (sauf 1982). La tendance de cette sērie ētait diffērente de celle de la sērie des taux de capture commerciale, mais elle se rapprochait de celle de la série des taux de capture du capelan obtenus au cours des relevés de poisson de fond.

## Introduction

Since the inception of the offshore capelin fishery in SA2 + Div. 3 K in 1972, substantial research effort has been generated to assess the status of this capelin stock. Annual acoustic surveys have been conducted by the USSR since 1974 and by Canada since 1977. Incidental data on capelin have also been collected during Canadian groundfish trawl surveys in Div. 2J3K since 1977. There is also a large body of commercial fishery data and these data were used in sequential capelin abundance models (SCAM) during the late 1970's. Although the SCAMs have not been used in recent years, commercial catch rate data have been used during the 1980's in an attempt to assess the status of the stock. In recent years, a directed inshore fishery to supply ripe females for the Japanese market has developed and research and commercial fishery data are now routinely collected during the spawning season.

It is the purpose of this paper to summarize pertinent data from the various offshore research activities and from the commercial offshore fishery to aid in assessment of this capelin stock. Besides comparing trends in abundance from various sources, timing and distribution of acoustic surveys are compared to other indicators of distribution to determine the efficacy of these acoustic surveys.

## Catch trends

The capelin fishery in NAFO SA2 and Div. 3K was, until 1972, a small inshore domestic fishery occurring during the spawning season. In 1972, substantial offshore catches were reported. These catches peaked in 1976 at $212,000 \mathrm{t}$ and declined during the late 1970's to $11,000 \mathrm{t}$ in 1979. During 1980-82, the only directed offshore catches were taken in an experimental USSR fishery. In most years, the offshore fishery occurred during August-December with peak catches occurring in September-November (Fig. 1). During 1972-78, catches occurred in both Div. 2 J and and 3 K but since 1979 , most of the catches have been taken in Div. 2J. In recent years, a small directed inshore roe fishery during June and July has occurred.

The offshore fishery first came under quota regulation in 1974 and the inshore fishery in 1982. Catches and TACs ('O00 t) since 1975 are shown below.

| Offshore |  |  |  |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| TAC | 160* | 160* | 212* | 212 | 75 | 5 | 10 | 10 | 10 | 17 | 17 |
| Nominal catch | 198 | 214 | 150 | 53 | 11 | 5 | 10 | 10 | 11** | 16** | 17** |
| Inshore |  |  |  |  |  |  |  |  |  |  |  |
| TAC |  |  |  |  |  |  |  | 3 | 11 | 8 | 8 |
| Nominal catch | 1 | 2 | 2 | 2 | 1 | 1 | 2 | 4 | 4 | 7** | 7** |

[^0]A. Canadian Acoustic Surveys and Commercial Fishery Distribution and Timing

Canadian acoustic surveys in Div. 2J3K have been conducted since 1977 but because of technical reasons, the estimates of capelin biomass prior to 1981 are considered very unreliable (see Stevens et al. 1985 for a more detailed discussion) and are not used in comparing status of the stock. In recent years, the survey design has become more rigorous by a) adopting a zig-zag survey design with equal transects thereby permitting calculation of variance estimates (Nakashima 1981), b) covering approximately the same area each year, and c) conducting the survey at about the same time each year.

The offshore capelin fishery in Div. 2J3K has in most years occurred during August-December (Fig. 1). During 1972-78 catches were taken in both Div. 2J and 3K, but since 1979 catches have been taken mostly in Div. 2J.

To determine whether the Canadian acoustic surveys are covering the capelin distribution, the area covered by the acoustic surveys was compared to the area fished by the USSR commercial fleet. This assumes that the commercial fleet fishes all areas in which capelin occur in quantities great enough to satisfy the needs of the fleet. This assumption may be violated; the quotas in this area have been relatively low in recent years, and therefore the fleet may be concentrating in areas where experience has shown that catch rates will be highest. Samples from the USSR fleet are collected by the Fisheries Cooperative Research Section in St. John's and the distribution of the fishery is therefore representative of the samples collected by observers and processed by the

Pelagic Section in St. John's. In collecting and processing samples, the aim is to collect and process two samples per week from each area (roughly $30 \mathrm{nmi} \times 60 \mathrm{nmi}$ ) of the fishery. The actual number of samples collected and processed and the proportion of observed catch to total catch is given in Table 1. In months where over 1000 t of capelin were caught, $77 \%$ had over $25 \%$ of the catch observed and $41 \%$ had over $50 \%$ of the catch observed. There were no months in which catches exceeded 1000 t that samples were not collected. It seems reasonable then that the distribution of samples from the commercial fishery provides an adequate representation of the distribution of the commercial fishery itself.

Plots of the distribution of commercial catches, by month, and the areas surveyed by the GADUS are shown in Figures 2-8. It is obvious that the GADUS acoustic surveys cover a wider area than that fished by the commercial fleet.

The commercial fishery since 1979 has operated from August to December in some years but in all years operates during September and October (Fig. 1, Table 1). In Div. 2J, where most of the catch has occurred since 1979, catch rates are usually good during September and October (Table 2). Monthly catch rates for large Soviet refrigerator trawlers (Bakanev 1981) indicate that in the early years of the fishery, catch rates were highest in the first months of the season (Table 3). In recent years, capelin have not been fished extensively during August. It is not known whether the changes in monthly catch rate trends reflect changes in capelin distribution and/or schooling or changes in fleet deployment. Given that the fleet has become much smaller since quotas were lowered and licencing has become more rigorous since extension of jurisdiction, the latter is a likely possibility.

Prior to 1981, GADUS acoustic trips were in late October and early November but since 1981, these surveys have been of 3-4 weeks duration during late September and early October. Thus, based on the data from the commercial fishery, it would appear that these surveys are conducted at a time appropriate to estimate capelin abundance.

## Age Compositions

Because recruitment is important in determining the mature spawning biomass of capelin, the age compositions from the commercial fishery and acoustic surveys provide valuable information on relative year-class strengths. To compare the age compositions from the two sources, the samples from the USSR fishery have been grouped to correspond to the survey blocks. Because the commercial samples are often collected over several months from any one survey area while catches are collected on a monthly basis, catches were weighted by the number of samples. For example, during 1985, all commercial samples were from NAFO Div. 2J and those from within
the survey area were from Blocks C and D. All September and October samples were from Block $C$ thus the total catch by USSR trawlers for these months was included in the analysis. For November, six samples were from Block C and four from Block D; therefore $60 \%$ of the November catch was entered for Block C samples and $40 \%$ of the catch for the Block D samples. The results of the comparisons for years 1979-85 are given in Tables 4-10.

The age compositions in these tables indicate that the Canadian fishing gear catches a higher proportion of one-year-olds, perhaps because of the fine-mesh liner in the survey gear. Age compositions for age 2 and older only were calculated for each data set and these age compositions are given on the second line of each cell in Tables 4-10. There are differences in labelling of survey blocks from year to year but in all tables the blocks are arranged from south to north.

Sampling was not extensive during the early years of the Canadian surveys. The low sampling rates for 1979 and 1980 were the result of relatively low biomasses of capelin during these two years and fishable concentrations were not detected often during the surveys. The sampling rate has increased since 1982 and age compositions derived for recent years are probably more representative of the population surveyed. For the last three years there is a higher proportion of one-year-olds in the southern part of the survey area. In fact, there is a dramatic drop in the proportion of one-year-olds in the most northerly block, north of approximately $54^{\circ} \mathrm{N}$.

In the last four years, 1982-85, the Soviet fishery samples and Canadian research samples agree when identifying the relative strengths of year-classes, with the exception of 1983. In that year, three-year-olds were slightly more prominent in Soviet samples in Block C while in the same area, Canadian samples identified two-year-olds as dominant. In some years and blocks (eg. 1982 Blocks F and G and 1985 Block D), agreement is very good. In years and blocks when agreement is not as good, the proportion of two-year-olds is usually higher in Canadian surveys with the proportion of three-year-olds higher in the Soviet fishery data.

While the Soviet commercial fishery generally operates over a smaller area than the Canadian research vessel surveys, the commercial fishery extends over a longer time period. Monthly age compositions were calculated from the Soviet fishery and are shown in Table 11. Two-year-olds dominate in most years. In 1979, 1980, 1983 and 1984 the proportions of two-year-olds in the catches increase during the fishing season. In 1982, this trend occurs during August through October but in November the proportion of two-year-olds declined. There was no trend in 1985 and the trend is opposite in 1980. Fishing occurred in only two months in 1980 and the dominance of age groups in the samples changed over those months. In September, three-year-olds dominated while in 0ctober two-year-olds dominated. The fishery occurred in a very restricted area in 1980 compared to other years. The catch rate estimates for 1980 were considered to be overestimated (Anon. 1981).

During 1984, there was a dramatic increase in one- and two-year-olds in the November age compositions and during that month fishing occurred more to the south of Div. 2J. During December, fishing occurred in Div. 3K and the age compositions of one- and two-year-olds, while declining somewhat from the November 2 J estimates, remained higher than those from September and October in 2 J .

Age compositions from the commercial offshore fishery in Div. 2J3K, from the USSR fleet, are given in Figure 9.
B. Canadian Groundfish and Acoustic Surveys

Stratified-random groundfish surveys in Div. 2J3K have been conducted by GADUS ATLANTICA in most years immediately after the capelin acoustic survey. A preliminary examination of the catch information indicated that capelin were rarely taken deeper than 500 m and the following analyses concentrate on strata 500 m and less. Catches of capelin were also very low in 1977 and 1978 and these years were not included in most of the subsequent analyses.

Catch rates (average no./set) of capelin in these surveys are given in Tables 12 and 13. Survey blocks were plotted on strata charts and visually examined and divided in three categories; no coverage by the acoustic survey, less than $50 \%$ of an individual stratum covered by the acoustic survey (marked with *), and more than $50 \%$ of an individual stratum covered by the acoustic survey (marked with **). The results are given in Tables 12 and 13. In some years and in some strata, very large individual catches were recorded. Most catches of capelin consisted of a few individuals although a few catches of hundreds or thousands of individuals occurred. To illustrate the effect of large catches on the catch rate, the largest catch, if it exceeded 3000 fish, was replaced by the next largest catch.

Using this visual comparison, the acoustic coverage of strata containing capelin during the groundfish survey is generally good in Div. 2 J but not so complete in Div. 3K. The strata in Div. 3K were further divided into those strata covered by the acoustic surveys (Strata 620-627) and those strata not usually covered by the acoustics survey (Strata 628-640) (Table 14). In all years except one (1980) the catch rates are higher in those strata covered by the acoustic survey although the ratio of catch rates between the areas is quite variable.

Some insight into capelin distribution can be obtained from cod feeding (Lilly 1984). Lilly examined cod feeding data from 1977-82 and used data from 1981 to illustrate spatial variability of cod predation on capelin. Predation of capelin was most intense on Hamilton Bank but also
occurred in other areas, including Funk Island Bank (i.e. the area not covered by acoustic surveys). The variation in total stomach fullness was largely a reflection of capelin distribution. He noted that similar patterns in total fullness index and partial fullness index for capelin were observed in 1980 and 1982. A similar geographic pattern in Greenland halibut predation on capelin was reported for the years 1981 and 1982 (Bowering and Lilly 1985), with some predation on capelin on Funk Island Bank but with most intense predation on Hamilton Bank and on or near the coastal shelf off southern Labrador and northern Newfoundland.

Because of increasing acoustic noise over greater depths, the distribution of capelin by depth is important in acoustically surveying capelin. There is a general decrease in catch rates of capelin with greater depth (Table 15) and in most years, catch rates are much greater in depths less than 300 m . There is a similar trend for Div. 2 J when the proportion of sets with capelin is examined (Table 16).

Capelin are known to undergo dynamic vertical migrations, usually dispersing and moving into the surface layers at night and schooling at greater depths during the daytime. Thus, the groundfish survey data were divided into day ( $0730-1630$ NST) and night sets. In five years out of seven, there was a higher proportion of sets with capelin during the day (Table 17) for each division and the divisions combined. However, this did not always happen in the same year eg. 1981. Nevertheless, catch rates by division were calculated for day sets (Table 18).

Trends in catch rates are quite different when comparing catch rates from all data and from daytime sets only. When considering all catches, the catch rates since 1982 have been relatively low with higher catch rates in 1980 and 1981. With only daytime catches, catch rates are relatively low in 1983-85 with higher catch rates in 1981 and 1982.

Samples were available for only a few groundfish catches (Table 19). The age compositions were not strikingly different from age compositions from the Canadian acoustic surveys or the commercial fishery although there appeared to be a higher proportion of older ages in the catches.
C. Abundance Indices
a) Commercial Catch Rates:

Commercial catch rates have been calculated from a number of different sources. One series (USSR/FRC in Table 20) consists of estimates from Seliverstov and Serebrov (1979) for the years 1972-78 inclusive and for 1979-84 estimates are from the Canadian Observer Program (Foreign Cooperative Research Section, D. Kulka, pers. comm.). The estimates for 1972-78 are from BMRT-A class trawlers whereas the estimates for 1979-84 are from USSR Tonnage Class 7 trawlers but it is not known whether these trawlers are BMRT-A Class. This series has been taken as indicative of trends in capelin abundance in Div. 2J3K (see CAFSAC Advisory Document 84/17)).

A catch rate series (1972-84) was also calculated using data from NAFO Statistical Bulletins for USSR trawlers Tonnage Class 7 (TC7) in which capelin comprised $>50 \%$ of the catch (TC7 in Table 20).

Another catch rate series (Table 20) was generated using data from NAFO Statistical Bulletins, most recent NAFO information from 1983 and 1984, preliminary catch data from 1985, and 1985 catch/hour data from FCR in a multiplicative model (Gavaris 1980). The analysis was slightly different from that presented previously (Carscadden et al. 1985) in that data were not included when there were less than two data points (compared to five last year) and the catch rates calculated this year are actual rates rather than relative rates. Details of the analysis are given in Tables 21 and 22 and the results are depicted in Figure 10. Significant differences occur between gears, months and years but not between NAFO Divisions.

Catch numbers (Table 23) and effort values (Table 21) from the multiplicative model were used to calculate catch rate-at-age indices (Table 24). Because of annual differences in maturation rates, emphasis on catch rates at age 2 only as an indicator of capelin abundance may be misleading. However, most capelin have matured by ages 3 and 4, therefore, an examination of a year-class at ages 2 and 3 would probably be more appropriate in assessing year-class strength. This has the disadvantge of yielding less information on the 1983 year-class which will be an important year-class in the 1986 fishery.
b) Acoustic Surveys:
i) USSR Acoustic Surveys

USSR acoustic surveys have been conducted annually (except for 1981) since 1974 and the results have been published in the NAF0 Research Document series. Since the authors normally produce a biomass estimate in tons as well as the total numbers of capelin estimated and the age composition, it is possible to estimate the numbers of fish by age. Unfortunately in many cases, the estimates must be considered approximate since the age compositions are often provided only as histograms and reading them with any accuracy is difficult. Bakanev (1980) provided a document summarizing age compositions in tabular form but the sample sizes and the age compositions are sometimes very different from those in the original papers even taking into account the difficulty in reading the histograms in the originals. The estimates of numbers at age from the Soviet surveys are given in Table 25 using both the original age compositions and those from Bakanev (1980). Relative year-class strengths are given in Table 26 and biomass estimates are given in Table 27.

The estimates of abundance of year-classes in 1982-84 surveys indicate that at age 2, the 1981 year-class was strongest followed by the 1980 and 1982 year-class (no estimates are available for 1979 year-class). At age 3, the 1981 year-class was very weak compared to the 1979 and 1980 year-classes. Based on the entire time-series, the 1973 year-class was the strongest at ages 2 and 3 with the 1981, 1980 and 1982 next in strength at age 2 and the 1971, 1979 and 1980 next in strength at age 3.

Generally the USSR surveys cover approximately the same area as the Canadian surveys. A common comment in their reports is that their estimates are underestimates because they cannot survey inside the Canadian territorial zone where there believe capelin occur. Their surveys occur usually in October or November, a notable exception being the 1984 survey when the survey occurred in December. They attribute the low estimates in 1984 to the lateness of the survey and the occurrence of fish within the Canadian territorial zone (Bakanev and Gorchinsky 1985).
ii) Canadian Acoustic Surveys

Biomass estimates and numbers at age from the Canadian acoustic surveys are given in Tables 27 and 28, respectively.

From the Canadian surveys, the 1979 year-class was most abundant at age 2 followed by the 1982 and 1983 year-classes. At age 3, the 1978 year-class appeared strongest followed by the 1981, 1982 and 1980. Unfortunately, there was no estimate available from the 1982 survey, a critical year in evaluating the strengths of the 1979 and 1980 year-classes.
c) Summary of Abundance Indices:
i) The commercial catch rates (Fig. 11) show a similar pattern especially since 1977 when the dominant gear has been TC7 USSR midwater trawlers. These estimates show a decline through the late 1970's and then a general increase since then (ignoring the 1980 value - see also the confidence intervals around the 1980 point in Fig. 10). There is a dramatic increase in catch rate between 1984 and 1985 and the 1985 catch rate is the highest on record.

Concern about the comparability of catch rate estimates between the period 1972-78 and 1979 to the present has been expressed before (see eg. Carscadden et al. 1985). Since 1979, most of the catches have occurred only in Div. 2 J although the results of the multiplicative model indicate that differences between divisions are not significant. However, the size of the catch and presumably the fishing fleet is much smaller than during the mid 1970's. Thus, it is possible that a smaller fleet could operate and sustain relatively good catch rates even if the stock was lower than in the 1970's.
ii) Groundfish Surveys:

Catch rates (no./tow) from groundfish surveys differ primarily in which year from 1979 to 1985 had the highest catch rate. Depending on how the data are treated, 1980, 1981 or 1982 exhibited the highest catch rates. Information from other sources indicates that the 1979 and 1980 year-classes were more abundant than year-classes immediately prior and this observation, when taken with the age compositions of capelin caught in the groundfish survey, would be consistent with high catch rates in 1981 and 1982. If this were the case, then the catch rates from daytime catches would probably be considered more reliable. In this case, catch rates in 1983, 1984 and 1985 for 2 J 3 K combined have shown a slight increase but they are well below the 1981 and 1982 catch rates.

All 2J3K combined catch rates show an increase from 1984 to 1985. The increase in catch rate between 1984 and 1985 is more dramatic for Div. 3K than Div. 2J.

Because of the known diel migrations of capelin, catch rates of capelin in bottom trawls are probably of limited use as abundance indicators and the incidence of capelin in bottom trawl catches is probably more indicative of capelin distribution. Capelin are reported to move from Div. 2 d to Div. 3K in November and December (eg. Bakanev and Gorchinsky 1985). What effect such a migration would have on the catch rates is unknown; the groundfish surveys generally cover Div. 2 J in November and Div. 3 K in December.
iii) Acoustic Estimates:

The USSR time series is fairly long and generally follows the trend of the commercial catch rate series. Unfortunately there is no 1985 value available and there is no estimate for 1981.

The Canadian estimates are available only from 1981 and a key year, 1982, is missing. The annual trends are different from the commercial catch rate series. The estimates from 1983, 1984 and 1985 are much lower than the 1981 estimate, a pattern more consistent with the groundfish catch rate pattern. However, the 1985 Canadian acoustic estimate is lower than the 1984 estimate and this decline is the opposite from all of the other abundance indices. The timing and rate of migration of capelin from Div. 2 J to Div. 3 K is unknown. The catch rates of capelin in Div. 2 J during groundfish surveys have not changed between 1983 and 1985 while the proportion of groundfish sets with capelin increased. In Div. 3 K the proportion of sets with capelin and catch rates increased between 1984 and 1985. It is possible that a greater proportion of capelin had already moved to Div. 3K outside the area surveyed acoustically and were not detected during the 1985 Canadian survey (see Table 14).
